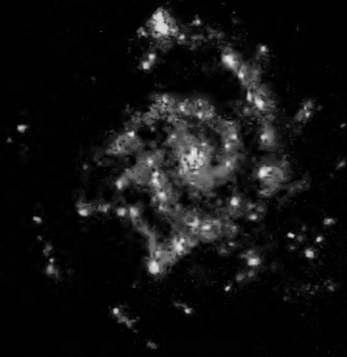
Scientific and Technical Aerospace Reports



An Abstract Journal

Volume 32, Number 6
June 1994
N94-22702 to N94-25542

The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

Linthicum Heights, MD 21090-2934

Scientific and Technical Aerospace Reports

STAR

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
  - Subject
  - Personal author
  - Corporate source
  - Contract number
  - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON, and through DIALOG as the Aerospace Database.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **2153**

02 AERODYNAMICS **2165**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also 3*4 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **2172**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **2174**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **2176**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **2186**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **2186**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **2190**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **2192**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **2194**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **2195**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **2196**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **2198**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **2199**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING.... **2201**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE 2203
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION 2208
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER 2209
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) 2222

24 COMPOSITE MATERIALS 2226
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY 2231
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS 2238
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS 2252
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS 2264
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING 2266
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) 2267
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR 2273
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING 2306
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER 2315
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY 2342
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS 2347
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING 2351
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY 2371
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS 2374
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) 2381

43 EARTH RESOURCES AND REMOTE SENSING 2381
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION 2389
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION 2396
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS 2400
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY 2407
Includes weather forecasting and modification.

48 OCEANOGRAPHY 2417
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) 2420

52 AEROSPACE MEDICINE 2423
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES 2427
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT 2429
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY 2444
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) 2444

60 COMPUTER OPERATIONS AND HARDWARE 2444
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE 2447
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS 2465
Includes computer networks and special application computer systems.

63 CYBERNETICS **2469**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **2478**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **2493**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **2497**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **2523**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **2523**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS **2525**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **2530**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **2540**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **2541**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **2548**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **2555**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **2568**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **2571**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **2585**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **2588**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS **2595**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY .... **N.A.**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **2596**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) .... N.A.

89 ASTRONOMY 2598
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS 2601
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION 2605
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS 2623
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION 2629
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

UNSTEADY JET FLOW COMPUTATION TOWARDS NOISE PREDICTION Final Report
Woo-Yung Soh Jan. 1994 17 p Presented at the 32nd Aerospace Sciences Meeting, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(Contract NAS3-25266; RTOP 537-02-22)
(NASA-CR-194449; E-8329; NAS 1.26:194449; AIAA Paper 94-0138)
Avail: CASI HC A03/MF A01

An attempt has been made to combine a wave solution method and an unsteady flow computation to produce an integrated aeroacoustic code to predict far-field jet noise. An axisymmetric subsonic jet is considered for this purpose. A fourth order space accurate Pade compact scheme is used for the unsteady Navier-Stokes solution. A Kirchhoff surface integral for the wave equation is employed through the use of an imaginary surface which is a circular cylinder enclosing the jet at a distance. Information such as pressure and its time and normal derivatives is provided on the surface. The sound prediction is performed side by side with the jet flow computation. Retarded time is also taken into consideration since the cylinder body is not acoustically compact. The far-field sound pressure has the directivity and spectra show that low frequency peaks shift toward higher frequency region as the observation angle increases from the jet flow axis.

Many colleges and universities throughout the United States offer outstanding programs in aerospace engineering. In addition to the fundamentals of aerodynamics, propulsion, flight dynamics, and air vehicle design, many of the best programs have in the past provided students the opportunity to design and fly airborne experiments on board various types of aircraft. Sadly, however, the number of institutions offering such 'airborne laboratories' has dwindled in recent years. As a result, opportunities for students to apply their classroom knowledge, analytical skills, and engineering judgement to the development and management of flight experiments on an actual aircraft are indeed rare. One major reason for the elimination of flight programs by some institutions, particularly the smaller colleges, is the prohibitive cost of operating and maintaining an aircraft as a flying laboratory. The purpose of this paper is to discuss simple, low-cost, relevant flight experiments that can be performed using readily available general aviation aircraft. This paper examines flight experiments that have been successfully conducted on board the NASA Lewis Research Center's T-34B aircraft, as part of the NASA/AIAA/University Flight Experiment Program for Students (NAUFEPS) and discusses how similar experiments could be inexpensively performed on other general aviation aircraft.

The most recent scientific results from space exploration carried out by the Jet Propulsion Laboratory (JPL) are discussed. To aid understanding of these results, a brief background of JPL's history is presented, followed by a description of the Deep Space Network, JPL's system of antennas which communicates with spacecraft. The results from the missions of Voyager 1 and Voyager 2 are described. The atmosphere, rings, satellites and magnetospheres of Jupiter, Saturn, Uranus and Neptune are discussed with particular emphasis on novelty of the discoveries and the challenges encountered in explaining them. A brief discussion of the impact of spray research upon space exploration follows. This is because most recently launched missions used liquid fueled rockets to escape Earth's gravity. A summary of future missions and the National Aeronautics and Space Administration's new policies is presented in the conclusion. ISA

Rocket propulsion has made a fundamental contribution to change in the human condition during the second half of the 20th Century. This paper presents a survey of the basic elements of and future prospects for liquid rocket propulsion systems, with emphasis placed on their bipropellant engines, which have contributed profoundly to the successes of this 'aerospace century.' Many technologies had to reach maturity simultaneously to enable our current progress: materials, electronics, guidance and control, systems engineering, and propulsion, made major contributions. However, chemical propellants and the engine systems required to extract and control their propulsive power successfully are at the heart of all that humankind has accomplished through space flight and the use of space for the betterment of all. And it is a fascinating story to tell. ISA

This paper describes and emphasizes the fundamental advances, achieved during the last two decades, in three important areas which have a central role in modern rotorcraft design. The topics considered are: (1) helicopter aeroelasticity, (2) aeromechanical problems, and (3) vibration and its alleviation using active controls. Each topic contains background to provide the reader with a certain perspective, illustrative examples and speculation on future research needs. ISA

The operational value of unmanned air vehicles (UAV) was clearly demonstrated by the use of the Pioneer UAV during the recent Gulf War. After sifting through operational data from Desert Storm, U.S. Army, Navy, Marine and Air Force planners agree that there is a validated requirement for future battlefield doctrine and tactics, that employ unmanned aerial vehicle systems. These systems will be deployed to help different users by determining enemy positions and, equally important, accurately tracking fast moving friendly troops. Emerging technologies such as artifical intelligence, data fusion, long range communications will influence the design and operation of future UAV systems. The presentation will try to present future UAV developments in the postwar environment of the Operation Desert Storm from operational and technology aspects. ISA

THE PLASTIC RESPONSE OF A CYLINDRICAL SHELL SUBJECTED TO AN INTERNAL BLAST WAVE WITH A FINITE WIDTH SHOCK FRONT c39

Y. Kivity, C. Florie, and H. Lenselink *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 89-102 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

This paper considers the plastic deformation of a thin cylindrical shell subjected to an internal explosion. It is assumed that the explosive charge is placed on the axis of symmetry of the shell so that an axisymmetric blast wave is produced. The shell response is calculated assuming an elastic-perfectly plastic material. The plastic response is evaluated for two types of loads. In the first type, the blast is assumed to have an ideal shock front with a discontinuous jump to the peak pressure. In the second type of loading, the shock front has a finite rise-time. This type of loading was introduced to study the effect of finite width shock fronts. Such finite width shock fronts are typical of hydrocode calculations when simulating problems involving blast waves and their interactions with adjacent structures. It is found that for equal impulse loads, the numerical rise-time reduces the shell plastic response significantly. Numerical calculations with a three-dimensional hydrocode are presented to illustrate the analytical results. A generalization of the analysis is given which may be used to determine the required mesh resolution of a hydrocode calculation in order to obtain a prescribed accuracy in the shell response. ISA

A 0.3-m diameter hypersonic shock tunnel has been designed and constructed to investigate the effect of a thin layer of a separating gas on the performance of the tunnel when operating in the equilibrium interface condition. The separating gas is placed between the drive gas, He, and the test gas, air. Preliminary experiments employing He, Ar and SF6 as the separating gases indicate a strong dependence of the final equilibrium interface pressure on the kind of gas used. These experiments showed that when SF6 is used, the highest equilibrium pressure is attained and that the time required to reach this pressure is the shortest when compared with the other two gases tested. It was observed that the separating gas acts as a gaseous piston enhancing the compression provided by the moving He/air interface. Tests involving the CO2 laser radiation absorption in SF6 were also conducted. These tests revealed not only the arrival of the gaseous piston at a given shock tunnel station but also the existence of SF6 leakage through the boundary layer. ISA

The time-dependent characteristics of the hypersonic flow of a detonable gas mixture in the stagnation region of a blunt-nosed body and blunt face of a forward facing step are studied using approximations based on inviscid analysis. In this investigation the approximation that at hypersonic speeds the flow in the stagnation region, behind the normal shock wave which is established in front of the blunt face of the model, can be considered to be at 'constant density' is used. Both of these approximations may be justified for very high Reynolds number flow at hypersonic speeds. In this analysis, it is shown that using the time-dependent flow equations which include the heat addition due to the chemical reactions, it is possible to develop a second-order differential equation for the instantaneous temperature. The stability characteristics of this governing equation are analyzed for the zero-order and first-order chemical reaction cases so as to determine the stability boundaries of the detonation phenomena in terms of the flow and the chemical reaction parameters. These dynamic characteristics are studied by the examination of the phase diagrams. The stability characteristics are determined by the analysis of the linearized equations. The calculated eigenvalues of the solutions are used to define both the stability boundaries and the oscillation frequencies. ISA

The presentation gives an overview of CFD (computational fluid dynamics) activities at the TASHAN Engineering Center of Israel Aircraft Industries (TECIAI), emphasizing new features in CFD technology. The first part starts with the description of purposes of industrial CFD at TECIAI. It then introduces the main codes developed 'in-house' during 1977-92, and explains the use of CFD codes in a typical cycle of CFD-aided aircraft design. The second part is devoted to state-of-the-art CFD technology with a number of typical applications given. Applications include complete aircraft analysis by a Multigrid Euler Code and incompressible 2-D Navier-Stokes calculations. ISA

The effect of the damping coefficients of stores, being released from a parent aircraft, on their trajectories was quantitatively analyzed. Trajectories which were obtained at the Israel Aircraft Industries (IAI) four-foot trisonic wind tunnel by using the Captive Trajectory System (CTS), were recalculated for various dynamic coefficients. Three types of stores were tested. The first store was an M117, which has an axisymmetric shape and is statically stable. The second type was a Multiple Ejection Rack (MER), which was asymmetrically loaded, and the third type of store was an MER which was loaded symmetrically. Two methods were utilized to recalculate the trajectories. The Zero-Order Correction (ZOC), in which the static coefficients were not corrected, and the First-Order Correction (FOC), in which the static loads were linearly extrapolated according to the corrected positions of the store. The main objectives of this study were threefold: (1) to study the effect of a particular damping coefficient on a trajectory which was obtained by the CTS; (2) to characterize the effect of the damping coefficients with respect to the nature of the store, namely, symmetric or non-symmetric, and (3) to compare the off-line correction, ZOC and FOC, with the original trajectories which were obtained by the CTS. Finally, the influence of the damping coefficients on the clearance in separation is quantitatively examined by a parametric study of the 6-degrees-of-freedom (6DOF) equations. ISA

Fundamental concepts of thrust-vectored fighter aircraft are defined and represented by novel designs of roll-yaw-pitch vectoring nozzles designed for maximized Post-Stall (PST) agility. The concepts are employed to formulate a unified mathematical phenomenology of PST, thrust-vectoring-induced supermaneuverability and to define standard agility comparison maneuvers in the PST domain. New dynamic scale rules generate an unorthodox methodolgy which combines full-scale jet-engine laboratory tests of new vectorable nozzles and inlets with flying 1/7-scale vectored models of F-22, F-15, F-16 and other, tailless, stealth, vectored models. A general vectoring control rate control rule is also defined. ISA

A combustion model for the burning of double-base propellants in the presence of hot plasma has been developed and used to predict burning rates at high ambient pressures. The theoretical model has been developed in order to gain some understanding of the experimental results obtained with a new gun design in which plasma is injected into the propellant cartridge in order to improve its ballistic performance. The hot plasma is introduced and mixed instantaneously with the products of combustion while increasing their temperature, thus augmenting the heat flux to the solid propellant and accelerating its burning rate. Based on the results of the present study, a numero-empirical model has been proposed to correlate the regression rate and the pressure by a simple form of the Vielle equation: dx/dt = A.p(exp n). The parameters A and n were found to be strong functions of the temperature. ISA

THE EFFECT OF HIGH ALTITUDE PRESSURE ON THE POWER AND EFFICIENCY OF AN AIRBORNE TWO-STROKE ENGINE c07

R. Harari and E. Sher *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 159-165 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

The effect of ambient pressure on the torque and fuel consumption characteristics of a crankcase-scavenged spark-ignition two-stroke engine has been investigated. The study includes an experimental part and a theoretical part. In the experimental part, the engine was tested under high-altitude conditions by using a simulator chamber where both the pressure at the inlet manifold and the pressure at the exhaust pipe were controlled separately. The influence of the simulation system on the engine performance has been investigated at sea level (s.l.) and the effect of the ambient pressure on the engine performance has been investigated in the range of 100 to 44 kPa, where the low pressure corresponds to a standard altitude of 21,000 feet (7 km). In the theoretical part a detailed computer program has been used to simulate the engine cycle under low ambient pressure. The computer program has been calibrated by using the s.l. experimental results. Very good agreement between the results of the theoretical model and the measurements under low ambient pressure conditions has been found over the entire range of operating conditions (100 to 44 kPa). An empirical correlation for the correction factor of the engine power has been suggested. The correction factor was found to be proportional to the ambient pressure raised to the power 1.5: ip/ip(sub s)= (P/P(sub s))(exp 1.5) Previous studies have suggested a power of 9/8 (1.125), but their validity was limited to a minimum ambient pressure of 70 kPa. The design procedure of hybrid engines which can meet mission requirements at optimized performance is presented. Multi-port grains are considered, and the effects of key operating and geometrical parameters on overall performance and on variations during engine operation are discussed. Excellent performance with an average specific impulse as high as 99% of the peak specific impulse, while keeping the thrust within 5% of the nominal value, in spite of the large geometrical variations during the grain combustion, are demonstrated for a LOX/HTPB system. This work describes the design of an altitude simulation facility for testing the AKM motor installed in the 'Ofeq' satellite launcher. The facility, which is controlled by a computer, consists of a diffuser and a single-stage ejector fed with preheated air. The calculations of performance and dimensions of the gas extraction system were conducted according to a one-dimensional analysis. Tests were carried out on a small-scale model of the facility in order to examine the design concept, then the full-scale facility was constructed and operated. There was good agreement among the results obtained from the small-scale facility, from the full-scale facility, and from calculations. ISA

NEARLY UNIFORM DEPLOYMENT/RETRIEVAL STRATEGY FOR SPACE TETHER SYSTEMS c18

E. M. Levin *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 185-195 (For primary document see N94-24241 06-01)

The nearly uniform deployment/retrieval strategy is advantageously applicable to the deployment or retrieval of many types of prospective space tether systems that include two satellites connected with a long flexible thread (tether). The basic idea of this strategy is to control the tether tension in such a way as to maintain a desired deployment rate. Normally, after a short initial transient process, the rate of deployment or retrieval approaches a 'cruising speed' which is then maintained up to the beginning of the final transient process. Under perturbations of a different nature (unexpected internal friction, non-gravitational external forces, etc.), the rate of deployment or retrieval is automatically adjusted in such a way as to compensate for the additional dynamic loads introduced. To generate the command tension, one has to know only the instantaneous deployed length of the tether and the rate of deployment or retrieval. In addition, the tension control of the same type is capable of damping out undesired in-plane and out-of-plane oscillations during stationkeeping. ISA

This paper presents near earth (less than 1000 km altitude) satellite autonomous navigation and orbit determination method, using measurements of the earth magnetic field. An orbit state vector comprised of six Keplerian elements enables the estimation of the instantaneous orbital elements by a relatively simple extended Kalman filter algorithm. The satellite position and velocity are computed as a function of the estimated orbital elements. The basic algorithm uses a 'measurement' of the magnetic field magnitude. Consequently, this algorithm is independent of altitude information. Simulation tests yielded an accurate Keplerian element estimation and a few kilometers of position estimation error. More complicated algorithms, which estimate drag and/or utilize altitude information, were tested. The basic algorithm was successfully applied to Earth Radiation Budget Satellite (ERBS) real data, and a modified version of this algorithm was applied to Gamma Ray Observatory (GRO) magnetometer readings to yield orbital elements, position, and velocity estimation. In both cases of real satellite navigation, the position was estimated within a few tens of kilometers. ISA

The concept of repairing cracked aluminum aircraft structures with composite patches was investigated both analytically and experimentally. Coupon tests provided basic mechanical properties of composite patches obtained using a repair procedure. A new surface treatment for bonding patches was developed and optimized. The damage repair process was substantiated by element and beam testing. Crack growth predictions were made using analytical stress intensity factors for the patched structure, and excellent correlation was obtained between observed and predicted values. Patches were very effective in reducing the crack growth rate. Cracks of unpatched element specimens which propagated to failure during random spectrum fatigue loading survived without failure for much longer lifetimes (approximately 3.5 times) under all tested environmental conditions. The process was substantiated by repairing and testing a defective beam element. ISA

This paper presents the summary of a multiphase experimental - analytical study of the post-buckling mechanical behavior of a graphite/epoxy integrally stiffened panel. The first phase of the study included cyclic compression tests in the post-buckling regime of flat panels stiffened by either 'I' or 'J' shaped stiffeners. Static residual strength of the panels after 250,000 cycles was greater than the reference strength; however, some stiffness loss was observed. A series of tests of individual stiffeners, identical to those in the panels, was also carried out and the results showed the same trends as had been observed in the panels. There were no cases of early failure during the cyclic tests. The second phase included an experimental study of the post-buckling behavior of cylindrical panels integrally stiffened in the axial and transverse directions. Panels were tested in cyclic compression, cyclic torsion, and in combinations of both. The panels were stressed through 40,000 cycles, damage was inflicted, and an additional 40,000 cycles were imposed. No damage development was observed. The third phase of the study included an analytical effort for the development of a computer code, PBCOMP, for the buckling and post-buckling analysis of stiffened laminated flat and curved panels. The results of this study clearly show a great potential for the safe use of stiffened graphite/epoxy panels in aircraft structures. ISA

DEVELOPMENT OF A DAMAGE TOLERANCE TOOL TO ANALYZE MULTIPLE-SITE DAMAGE IN AIRCRAFT STRUCTURE **c05**

A. Brot and A. Nathan *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 237-245 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

A multiple site damage (MSD) analytical model is presented that predicts the crack growth behavior of a series of cracks at a row of open holes. A coupon test program is described that serves to verify the accuracy of the analytical model. For both equal and unequal sized initial cracks, the analysis predicted lives that were 10-14% longer than the average test result. The results also show that, if MSD effects were to be neglected, a non-conservative error of nearly 100% would result. The results of a parametric study are presented that demonstrate when MSD effects are most significant. ISA

The computerized system, REPCOMP, developed for damage repair of composite structures, is an expert system for the design of damage repair. REPCOMP provides detailed repair instructions and drawings, taking into consideration strength and stiffness requirements as well as aerodynamics, weight, and other design considerations. The REPCOMP expert system is being developed for the two major paths in damage repair of composite structures, which are: permanent damage repair, suitable for long-term use in civil and military aircraft, and A/C battle damage repair (ABDR), suitable for field repair of military aircraft during battle. REPCOMP operates on a portable computer (pc), using the Microsoft Windows graphical environment. It is an independent system and can be used in any field repair base. Currently the program handles the ABDR path. ISA

Simultaneous state and input estimation is often mandatory in control systems with output feedback in the presence of unknown, systematic input signals. Guidance loops are a typical example for such systems. It has been shown in the literature that state and input estimation can be performed by switched observers for processes that satisfy a certain matching condition. There are, however, two major difficulties associated with this result: the matching condition is satisfied by only a few systems of practical importance, and the extension of the switched observer concept to the case of measurements which are corrupted by stochastic measurement noise is still an open question. In this paper, both issues are addressed. The stability of switched observers is proved for a larger class of deterministic systems. Subsequently, a stochastic state and input observer is derived that handles measurements with additive Gaussian distributed noise. This result merges the concepts of switched observers and covariance matching. The new observer is applied to an example of target maneuver estimation in a planar intercept scenario. ISA

DECENTRALIZED AUTONOMOUS ATTITUDE DETERMINATION USING AN INERTIALLY STABILIZED PAYLOAD **c13**

Yaakov Oshman and Michael Isakow *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 263-274 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

A novel method is introduced for the autonomous determination of the attitude angles of a mini remotely piloted vehicle (RPV) with an inertially stabilized payload. The method is based on measurements of rate gyros used to inertially stabilize the payload, and other data which are normally available from conventional aircraft-mounted sensors. These measurements are used to drive a decentralized estimation algorithm, which uses the aircraft/payload mathematical models to bound the estimation errors. Exploiting modern multi-processor computer technology, the new estimation algorithm comprises two extended Kalman filters (EKF) working in parallel, and a data fusion algorithm. Real-time simulation tests, incorporating a payload model with real rate gyros mounted on a three-axis flight table, have validated the feasibility of the concept. The presented theoretical and experimental investigation demonstrates that the estimation algorithm is capable of estimating the attitude angles with an estimation error not exceeding one degree, at ouput rates of 13 Hz, thus constituting an efficient and reliable replacement for the conventional vertical gyroscope. MAXIMUM LIKELIHOOD MODAL PARAMETER IDENTIFICATION AND REALIZATION OF STOCHASTIC SYSTEMS **c65**

Yaakov Oshman and Tal Mendelboim *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 275-286 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

A new maximum likelihood (ML) realization/identification technique is presented. The method is based on using the recently introduced Eigensystem Realization Algorithm (ERA) in combination with a stochastic adaptive filter/fixed-interval smoother. The resulting algorithm, called ML/ERA, is thus capable of estimating a minimal, internally balanced realization for a stochastic system whose process and/or measurement noise covariances are not necessarily known. Belonging to the ML class of algorithms, the new method is consistent and asymptotically efficient under reasonable conditions. Moreover, by using standard statistical testing techniques, the user is able to assess the quality of the resulting estimates during the iterative estimation process. A numerical investigation of the performance of the new algorithm has shown a vast improvement over the performance of the original, unaugmented ERA. In cases where the ERA could not determine the system order because the data was completely masked by noise, the ML/ERA algorithm was able to identify the order and realize an accurate mathematical model of the system. Numerical examples, demonstrating the performance of the new algorithm, are included in the paper. ISA

The Pilot Evaluation System (PES) is a fixed-based, self-contained and autonomous system, designed for the screening of candidates for pilot training and the evaluation of candidates' chances for success as operational pilots. The PES evaluates and analyzes the performance of the candidate in simulated flight-like conditions. The skills evaluated by the PES are correlated with those needed for the successful completion of flight training. The PES was designed and developed at Israel Aircraft Industries (IAI)-TASHAN by a group of experts consisting of senior fighter pilots, psychologists, physicians, engineers, and flight instructors. The measurement of performance under intense workload serves as a basis for the prediction of future pilots' abilities. In the PES, workload is defined as the combination of loads imposed on subjects by a combination of tasks in a given environment. Some air forces have acquired a PES version for their own use, and they are presently validating its performance. As the data are clients' property, they cannot be presented in this paper. ISA

The Captive Trajectory System (CTS) is used primarily for prediction of store separation trajectories in close proximity to the parent aircraft. The system serves as a main tool in store separation analysis. Thanks to the high level of correlation between CTS results and flight test results, it has been suggested that the use of the CTS be extended to predicting the interference of the aircraft with the store and the effect on its ballistic range. In a two year effort, several stores were analyzed by means of the CTS predictions. The article presents a comparison between the CTS based prediction and flight test results for store range and trajectory. This comparison proves the adequacy of the prediction of aircraft effects on the store, as well as providing a good numerical prediction of the impact point. In addition, the flight test results verify the simulation's prediction that Mach number and store initial location (aircraft station and position on multiple rack) have a significant effect on aircraft interference with the store and on the ground impact point. Tests of composite cold-bonded and wet lay-up joints were performed for various loadings. The test results were completed by linear extrapolation and analyzed statistically by the controlled experiments method. Principal parameters concerning mechanical performance were identified and, accordingly, design improvements were recommended. ISA

Due to its strong construction, resistance to the marine environment, and projected service life, the S-2E Tracker aircraft was chosen for its operational performance to be extended through re-engining, systems upgrading, and integration of new avionics. The aircraft was originally designed for carrier based antisubmarine missions and is ideally suited for efficient and effective maritime patrol. With the installation of rapid-response, 1645 horsepower, Garrett TPE331-15AW turbo-propeller engines and five blade composite reversible propellers, the S-2E/turbine becomes a high performance aircraft with a greater climb rate and 50 percent reduction in fuel consumption over the original S-2E piston aircraft. Intensive flight tests have proven a dramatic increase in mission capability with increased area coverage and flight safety improvements. Israel Aircraft Industries (IAI) is conducting a program to retrofit S-2E Tracker aircraft with Federal Aviation Administration (FAA) and MIL-STD certified, state-of-the-art engines, avionics, and sub-systems. A simple control concept utilizing product of inertia is used to provide active nutation control of a reactive thrust control system of a geosynchronous momentum-based satellite. The reactive thrust control system itself is immune to sensor noise and thus prevents unnecessary thrust firings. Any nutation excitation is damped in a small number of nutational periods, with no fuel consumption. ISA

This paper addresses the ignition of porous composite boron-titanium particles. The model takes into account the exothermic reaction between boron and titanium particles within the composite particle. A possible reaction enhancement between boron and titanium sub-particles due to the sintering process has been considered. Calculations performed by using the present model showed a substantial shortening of the ignition process by adding some titanium to pure boron particles. Calculations using two models of boron oxidation reported in the literature were performed. A sintering model has been developed, taking into account the principal mechanisms of material transport, i.e., grain-boundary and volume dispersion. The theoretical results revealed a significant positive effect of internal condensed-phase reactions between B and Ti on boron particle ignition. ISA

A mathematical stability analysis is conducted to define the domain of operating conditions under which a combustion generated particle will be formed by coagulation of incipient particles (or clusters). Two opposing concurrent mechanisms are considered, namely: (1) growth by coagulation, and (2) simultaneous shrinkage due to sublimation or oxidation of the particle. These two mechanisms are incorporated in the discrete coagulation equations. Then, summations are carried out over all discrete sizes, once for the total number of incipient particles and once for the total mass. A particle is formed under conditions of growth in mass and a decrease in total number of incipient particles. The stability analysis is based on Liapunov's theorem. Various mathematical forms of collisional kernels are analyzed. Our results indicate that only enhanced collision rates (e.g., kernels of the form of beta(sub ij) is approximately i.j) will lead to an unstable rapid growth of particles. This observation is in agreement with the conclusions drawn by Harris et al., who employed collisional enhancement factors to fit their theoretical soot size distribution calculations to the data on soot particles obtained in a premixed ethylene flame. The ignition and combustion of special composite titanium/boron particles were studied experimentally. It is assumed that a small addition of titanium may result in appreciable enhancement of the boron ignition and combustion due to exothermic chemical interactions of titanium with oxygen and boron. The experiments were carried out in a flat flame burner. Composite B/Ti particles, 100-150 microns in size containing 13 wt. percent of titanium were injected into the flat flame products of different oxygen content. Noticeable intensification of the ignition and combustion of composite boron/titanium particles in comparison with similar boron particles was detected. ISA

MEAN STRESS MODELS FOR LOW CYCLE FATIGUE OF A NICKEL-BASE SUPERALLOY c39
Daining Fang and Avraham Berkovitz *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 374-386 Supported in part by Rolls-Royce Ltd., Derby, England (For primary document see N94-24241 06-01)
Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

The aim of this study was to relate observed Low Cycle Fatigue responses under asymmetric loading to mean-stress effects on the cyclic behavior and fatigue life of nickel-base Incoloy 901 superalloy at room temperature. Based on experimental data, a mean-stress-relaxation of mean-stress on the total strain range and on cyclic plasticity. It was found that cyclic softening and mean-stress relaxation began when plastic strain started to develop, and increased in importance with increasing strain range. Both depended on the plastic strain range rather than on monotonic plastic deformation. For any given strain ratio, there was a value of strain range corresponding to peak mean stress sustained. Beyond this strain range, mean stress relaxation began. A mean-stress strength constant, representing the apex on the sigma(sub m) axis of the Goodman diagram, was introduced in order to modify the Goodman criterion, resulting in a modified strain-life relation. Both the mean-stress-relaxation model and the strain-life model were evaluated against LCF testing data. ISA

The breakthrough provided by the recognition that the fracture mechanics quantity, delta K controls fatigue was of immense importance. The empirical Paris-type equations da/dn = C((delta K)/(delta K(sub 0)))(exp n) were used extensively for a long time and provide much information from experience. More than 70 of the Paris-type empirical relationships were developed. The empirical equations are more or less arbitrarily imposed on the experimental results to bring them into formal agreement with the measured data. Consequently, these are actual curve fitting equations - alternatives to the tabulated test data for which they were designed. In contrast to this, fracture kinetics descriptions are rigorously derived from basic principles of general validity. The fundamental processes of corrosion fatigue are a complex combination of corrosion and embrittlement chemical reactions, diffusion, and crack growth steps. It is of critical significance that the fracture kinetics description of crack growth includes the effects of the microstructure in quantitative expression. The validity of the fracture kinetics theory was demonstrated in extensive investigations; it was shown that for a large range of materials and imposed conditions, fatigue can be represented very well by the fracture kinetics constitutive law. To define the empirical and semi-empirical relations with microstructural and macroscopic quantities, three basic types are represented. ISA

EVALUATION OF THE FRACTURE RESISTANCE AND DURABILITY OF ADHESIVE BONDED JOINTS **c39**

H. Leibovich and V. Weissberg *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 402-408 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

A methodology to evaluate the fracture resistance and durability of adhesive bonded joints is presented. This method fills the gap between simple comparative tests such as Lap Shear ASTM D1002, Wedge Crack or Floating Roller Peel (Bell Peel) ASTM D3167 and quantitative data for design calculations. The analytical basis of the method consists of recently developed relationships between the stress intensity factor (SIF) and the stress concentration factor (SCF) which is unique for adhesive bonded joints for any bonded attachment geometry. The Mixed Mode Flexure (MMF) test specimen was found to be appropriate to the analytical method. MMF is also sensitive to interface properties and easily fabricated and tested. Experimentally, four different surface treatments were evaluated using the MMF test specimens. Testing was conducted at room temperature and at 70 C after exposure to 60 C, 95 percent RH (relative humidity). Lap Shear and Bell Peel test specimens were also tested and compared with the new method. The MMF test results showed the following outstanding advantages: (1) quantitative design data are available in contrast with Lab Shear and Bell Peel test specimens; (2) both modes, shear and tension, could be evaluated at the same time; (3) the MMF testing provides realistic geometry and mode of loading as in actual structures; and (4) the newly developed methodology proved to be sensitive for evaluation of surface preparation and durability for bonding. VIBRATIONS OF VARIABLE CROSS SECTION TIMOSHENKO BEAMS **c39**

Moshe Eisenberger *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 409-412 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

The Timoshenko beam model incorporates the effect of shear deformations and rotary inertia in the vibration response of beams. For constant cross section beams it was shown that the effect is dependent on the aspect ratio of the beams, and for beams with large ratios, the effect is small. Exact vibration frequencies for variable cross section beams are found using the dynamic stiffness matrix approach. The stiffness matrix is frequency dependent, and the natural frequencies are those that cause the matrix to become singular. Examples are given and compared with known results of beams with various taper ratios. ISA

The problem of inverse dynamics of a system of rods and a flexible beam was discussed and analyzed. The role of boundary and initial conditions was examined by analysis of the linear problem of an Euler beam. It was demonstrated that the solution of an Euler beam for a fully inverse dynamics (where all six constraints were imposed on one end of the beam) depends solely on the boundary constraints and does not rely on any initial conditions. In addition, the boundary functions in this case should be analytic, with an infinite number of derivatives. ISA

The evolution of a Burke-Schumann type of spray diffusion flame is examined. Full representation of transport, spray and combustion is allowed through use of nonunity Lewis numbers for the gaseous components, local pointwise multisize droplet distribution for the spray, and a finite chemical Damkohler number based on a single global chemical reaction. It is found that under certain operating conditions the transient behavior of the spray flame exhibits the phenomenon of flame separation, even though a steady state is ultimately attained. The local polydispersity of the spray is shown to be one of the factors affecting the appearance of the separated flamelet. ISA

EFFECT OF INITIAL DROPLET-SIZE DISTRIBUTIONS ON FUEL-VAPOR PROFILES IN A SHEAR-LAYER FLOW **c34**

D. Katoshevski and Y. Tambour *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 439-448 (SEE N94-24241 06-01) 25 Feb. 1993 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

The evaporation of a multisize (polydisperse) liquid fuel spray in a shear-layer between two parallel, unidirectional streams of unequal velocity was analyzed. The analysis is also applicable for a shear-layer between two radially spreading streams which share the same axis of symmetry. Similarity solutions are presented for the evolution in droplet size distributions across the shear-layer, and the effects of various initial droplet size distributions on the profiles of fuel-vapor concentrations are examined. A qualitative comparison between the present results for a typical computed total mass distribution of the liquid-phase and experimental results of the intensity of light scattering from droplets as reported by Lazaro and Lasheras shows similarity between the two profiles. This supports the assumptions and boundary-conditions employed in the present theoretical study. The general behavior of the theoretical SMD (Sauter Mean Diameter) distribution of the spray across the shear layer also compares well with the reported experimental results of Lazaro and Lasheras. MULTIPLE FLAMES IN COUNTERFLOW SPRAY COMBUSTION **c25**

N. Sarig and J. B. Greenberg *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 449-457 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

The formation of multiple flames in counterflow premixed spray combustion is studied in a new theoretical investigation. The fuel is introduced into the system in the form of a spray and vapor mixed homogeneously with oxygen and a diluent. Calculated results point to the possibility of the existence of three different modes of combustion depending on the ratio between fuel vapor to oxygen mass fractions in the injected stream and the vaporization Damkohler number of the spray. Three numerical models for predicting the aerodynamic performance of Modern Technology Propellers (MTP) are described. The models include a Blade-Element/Momentum model, a Lifting Line model, and a VLM (Vortex Lattice Method) model. These three models are simple and characterized by numerical efficiency. The first two models use two dimensional tabulated airfoil data to account for the compressibility, viscosity, and nonlinear airfoil characteristics. The models also include corrections for various effects such as tip effect, sweep, and induced tangential velocity. The results of the three models are compared with experimental results for two MTP designs, one with straight blades and the other with swept ones. The results are explained and discussed. ISA

Due to the loads that act along a helicopter blade, it experiences elastic pitch variations. These elastic pitch variations are the result of elastic torsion along the blade and the flexibility of the pitch control system. The use of a simplified model, describing these elastic pitch variations, which is appropriate for flight mechanics analyses, is presented. Parameters which determine the elastic pitch variations include: the blade torsional stiffness, cross sectional locations of the center of mass and aerodynamic center, the airfoil aerodynamic moment coefficient, pitch control system flexibility, and damping along the blade and of the control system. The influence of such parameters on trim position, stability and control derivatives, stability roots, and time response is presented. ISA

CONTINUOUS GUST RESPONSE AND SENSITIVITY DERIVATIVES USING STATE-SPACE MODELS **c08**

Arie Zole and Mordechay Karpel *In* Israel Society of Aeronautics and Astronautics, The 33rd Israel Annual Conference on Aviation and Astronautics 25 Feb. 1993 p 482-492 (For primary document see N94-24241 06-01)

Copyright Avail: Issuing Activity (Israel Society of Aeronautics and Astronautics, c/o Faculty of Engineering, Tel-Aviv Univ., Ramat Aviv 69978, Israel)

The dynamic response to atmospheric turbulence plays an important role in the design of flight vehicles. The presented work is an extension to the work on multidisciplinary optimization of aeroservoelastic systems using reduced-size models. The continuous-gust turbulence and the response parameters are represented in statistical terms by power spectral density (PSD) functions and root mean square (RMS) values. The time domain, state-space optimization model is extended to deal with gust excitation and to produce RMS response of section loads, structural velocities, and accelerations. Recommendations are given for the application of the physically weighted minimum-state aerodynamic approximation technique such that there is no need to increase the (relatively small) number of aerodynamic states beyond those required for stability analysis. The plant states are augmented by gust-filter states in a way that produces a dynamic system excited by white noise at the gust-filter inputs. This representation facilitates direct RMS computations by solving matrix Liapunov equations. Analytical expressions for the sensitivity derivatives of the dynamic matrix with respect to structural and control design variables yield another set of Liapunov equations which can be efficiently solved for many response derivatives. The suggested model is demonstrated to be considerably more efficient than classical frequency-domain models. ISA

A solution to nonlinear formulated problems using eigenfunctions computed by a linear free vibration solution is presented. The system of equations is extremely reduced compared with the finite element method. The solution is unique in its formulation as the governing equations represent the problem continuously and do not require an iterational solution over a tangent stiffness. Energy consideration is used and the Ritz method is applied to render the governing equations. The eigenfunctions are computed by a linear finite element code: MSC/NASTRAN. Several numerical examples are presented and compared with examples from the literature. ISA

The extensively used empirical models of plastic deformation, the sinh and power function law relations, are valid only in a limited range and are not suitable for extrapolation. At low stresses, the sinh either overestimates or greatly underestimates the strain rate. The power function relation, being the tangent of the logarithm of strain rate vs. logarithm of stress plot, is a fair approximation near to the inflexion point only. The constitutive law of plastic deformation provides a rigorous expression that describes the behavior of solids under the effects of both the applied stress and the temperature, for the full range of the applied stress. This publication is a collection of materials presented at a NASA workshop on guidance, navigation, controls, and dynamics (GNC&D) for atmospheric flight. The workshop was held at the NASA Langley Research Center on March 18-19, 1993. The workshop presentations describe the status of current research in the GNC&D area at Langley over a broad spectrum of research branches. The workshop was organized in eight sessions: overviews, general, controls, military aircraft, dynamics, guidance, systems, and a panel discussion. A highlight of the workshop was the panel discussion which addressed the following issue: 'Direction of guidance, navigation, and controls research to ensure U.S. competitiveness and leadership in aerospace technologies.' For individual titles, see N94-25097 through N94-25115.

General aviation today is a vital component in the nation's air transportation system. It is threatened for survival but has enormous potential for expansion in utility and use. This potential for expansion is fueled by new satellite navigation and communication systems, small computers, flat panel displays, and advanced aerodynamics, materials and manufacturing methods, and propulsion technologies which create opportunities for new levels of environmental and economic acceptability. Expanded general aviation utility and use could have a large impact on the nation's jobs, commerce, industry, airspace capacity, trade balance, and quality of life. This paper presents, in viewgraph form, a general overview of U.S. general aviation. Topics covered include general aviation shipment and billings; airport and general aviation infrastructure; cockpit, airplane, and airspace technologies; market demand; air traffic operations and aviation accidents; fuel efficiency comparisons; and general aviation goals and strategy. NASA began a multi-center study in January 1993 to examine options for providing the most cost effective space transportation system in the future. The key advanced avionics requirements for these vehicle concepts are envisioned to provide significantly improved operational efficiency and effectiveness. It is very desirable to have adaptive guidance, navigation, and control approaches that will allow launch and return in almost any weather condition. The vehicles must be able to accommodate atmospheric density variations and winds without software changes. The flight operations must become much more autonomous in all flight regimes like an aircraft, and preflight checkout should make use of the onboard systems. When the vehicle returns to the launch site, subsystem health must be known and maintenance tasks scheduled accordingly. Ground testing of most subsystems must be eliminated. Also, the health monitoring system must be designed to enhance the ability to abort the mission significantly and save the crew and the vehicle. The displays and controls must be much less complex than current systems and must significantly reduce pilot work load. It is important to have low power, light weight displays and controls. Rendezvous and docking and all flight phases must have autopilot capability to reduce pilot work load for routine operations and in abort situations. The vehicles must have the demonstrated ability to return to the launch site. Abort from all mission phases can put additional demands on the communications system. Derived from text

HIGHLY-RELIABLE FLY-BY-LIGHT/POWER-BY-WIRE TECHNOLOGY **c08**
Felix L. Pitts *In its* NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 85-95 (For primary document see N94-25096 06-01)
Avail: CASI HC A03/MF A04

This paper presents in viewgraph format an overview of the program at NASA Langley Research Center to develop fly-by-light/power-by-wire (FBL/PBW) technology. Benefits of FBL/PBW include intrinsic electromagnetic interference (EMI) immunity and lifetime immunity to signal EMI of optics; simplified certification; the elimination of hydraulics, engine bleed air, and variable speed, constant frequency drive; and weight and volume reduction. The paper summarizes a study on the electromagnetic environmental effects on FBL/PBW systems. The paper concludes with FY 1993 plans. CASI

DIFFERENTIAL GPS FOR AIR TRANSPORT: STATUS **c04**
Richard M. Hueschen *In its* NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 97-114 (For primary document see N94-25096 06-01)
Avail: CASI HC A03/MF A04

The presentation presents background on what the Global Navigation Satellite System (GNSS) is, desired target dates for initial GNSS capabilities for aircraft operations, and a description of differential GPS (Global Positioning System). The presentation also presents an overview of joint flight tests conducted by LaRC and Honeywell on an integrated differential GPS/inertial reference unit (IRU) navigation system. The overview describes the system tested and the results of the flight tests. The last item presented is an overview of a current grant with Ohio University from LaRC which has the goal of developing a precision DGPS navigation system based on interferometry techniques. The fundamentals of GPS interferometry are presented and its application to determine attitude and heading and precision positioning are shown. The presentation concludes with the current status of the grant. Derived from text

Langley Research Center was an early leader in simulation technology, including a special emphasis in space vehicle simulations such as the rendezvous and docking simulator for the Gemini program and the lunar landing simulator used before Apollo. In more recent times, Langley operated the first synergistic six degree of freedom motion platform (the Visual Motion Simulator, or VMS) and developed the first dual-dome air combat simulator, the Differential Maneuvering Simulator (DMS). Each Langley simulator was developed more or less independently from one another with different programming support. At present time, the various simulation cockpits, while supported by the same host computer system, run dissimilar software. The majority of recent investments in Langley's simulation facilities have been hardware procurements: host processors, visual systems, and most recently, an improved motion system. Investments in software improvements, however, have not been of the same order. Author

A SIMULATION STUDY OF CONTROL AND DISPLAY REQUIREMENTS FOR ZERO-EXPERIENCE GENERAL AVIATION PILOTS **c54**

Eric C. Stewart *In its* NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 147-175 (For primary document see N94-25096 06-01)

Avail: CASI HC A03/MF A04

The purpose of this simulation study was to define the basic human factor requirements for operating an airplane in all weather conditions. The basic human factors requirements are defined as those for an operator who is a complete novice for airplane operations but who is assumed to have automobile driving experience. These operators thus have had no piloting experience or training of any kind. The human factor requirements are developed for a practical task which includes all of the basic maneuvers required to go from one airport to another airport in limited visibility conditions. The task was quite demanding including following a precise path with climbing and descending turns while simultaneously changing airspeed. The ultimate goal of this research is to increase the utility of general aviation airplanes - that is, to make them a practical mode of transportation for a much larger segment of the general population. This can be accomplished by reducing the training and proficiency requirements of pilots while improving the level of safety. It is believed that advanced technologies such as fly-by-wire (or light), and head-up pictorial displays can be of much greater benefit to the general aviation pilot than to the full-time, professional pilot. PARAMETRIC UNCERTAINTY MODELING FOR APPLICATION TO ROBUST CONTROL **c08**

Christine M. Belcastro, B.-C. Chang (Drexel Univ., Philadelphia, PA.), and Robert Fischl (Drexel Univ., Philadelphia, PA.) *In its* NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 177-192 (For primary document see N94-25096 06-01)

Avail: CASI HC A03/MF A04

Viewgraphs and a paper on parametric uncertainty modeling for application to robust control are included. Advanced robust control system analysis and design is based on the availability of an uncertainty description which separates the uncertain system elements from the nominal system. Although this modeling structure is relatively straightforward to obtain for multiple unstructured uncertainties modeled throughout the system, it is difficult to formulate for many problems involving real parameter variations. Furthermore, it is difficult to ensure that the uncertainty model is formulated such that the dimension of the resulting model is minimal. A procedure for obtaining an uncertainty model for real uncertain parameter problems in which the uncertain parameters can be represented in a multilinear form is presented. Furthermore, the procedure is formulated such that the resulting uncertainty model is minimal (or near minimal) relative to a given state space realization of the system. The approach is demonstrated for a multivariable third-order example problem having four uncertain parameters. Author (revised)

HYPERSONIC VEHICLE CONTROL LAW DEVELOPMENT USING H(INFINITY) AND MICRON-SYNTHESIS **c08**

Irene M. Gregory, John D. McMinn, John D. Shaughnessy, and Rajiv S. Chowdhry (Lockheed Engineering and Sciences Co., Hampton, VA.) *In its* NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 193-208 (For primary document see N94-25096 06-01)

Avail: CASI HC A03/MF A04

Hypersonic vehicle control law development using H(infinity) and mu-synthesis is discussed. Airbreathing SSTO vehicles has a mutli-faceted mission that includes orbital operations, as well as re-entry and descent culminating in horizontal landing. However, the most challenging part of the operations is the ascent to orbit. The airbreathing propulsion requires lengthy atmospheric flight that may last as long as 30 minutes and take the vehicle half way around the globe. The vehicles's ascent is characterized by tight payload to orbit margins which translate into minimum fuel orbit as the performance criteria. Issues discussed include: SSTO airbreathing vehicle issues; control system performance requirements; robust control law framework; H(infinity) controller frequency analysis; and mu controller frequency analysis. ON-LINE EVALUATION OF MULTILOOP DIGITAL CONTROLLER PERFORMANCE **c08**

Carol D. Wieseman *In its* NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 209-220 (For primary document see N94-25096 06-01)

Avail: CASI HC A03/MF A04

The purpose of this presentation is to inform the Guidance and Control community of capabilities which were developed by the Aeroservoelasticity Branch to evaluate the performance of multivariable control laws, on-line, during wind-tunnel testing. The capabilities are generic enough to be useful for all kinds of on-line analyses involving multivariable control in experimental testing. Consequently, it was decided to present this material at this workshop even though it has been presented elsewhere. Topics covered include: essential on-line analysis requirements; on-line analysis capabilities; on-line analysis software; frequency domain procedures; controller performance evaluation frequency-domain flutter suppression; and plant determination. AIRCRAFT DIGITAL FLIGHT CONTROL TECHNICAL REVIEW **c08**

Otha B. Davenport and David B. Leggett (Wright Lab., Wright-Patterson AFB, OH.) *In* NASA. Langley Research Center, NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 243-250 (For primary document see N94-25096 06-01)

Avail: CASI HC A02/MF A04

The Aircraft Digital Flight Control Technical Review was initiated by two pilot induced oscillation (PIO) incidents in the spring and summer of 1992. Maj. Gen. Franklin (PEO) wondered why the Air Force development process for digital flight control systems was not preventing PIO problems. Consequently, a technical review team was formed to examine the development process and determine why PIO problems continued to occur. The team was also to identify the 'best practices' used in the various programs. The charter of the team was to focus on the PIO problem, assess the current development process, and document the 'best practices.' The team reviewed all major USAF aircraft programs with digital flight controls, specifically, the F-15E, F-16C/D, F-22, F-111, C-17, and B-2. The team interviewed contractor, System Program Office (SPO), and Combined Test Force (CTF) personnel on these programs. The team also went to NAS Patuxent River to interview USN personnel about the F/A-18 program. The team also reviewed experimental USAF and NASA systems with digital flight control systems: X-29, X-31, F-15 STOL and Maneuver Technology Demonstrator (SMTD), and the Variable In-Flight Stability Test Aircraft (VISTA). The team also discussed the problem with other experts in the field including Ralph Smith and personnel from Calspan. The major

conclusions and recommendations from the review are presented.

DEVELOPMENT OF HIGH-ANGLE-OF-ATTACK NOSE-DOWN PITCH CONTROL MARGIN DESIGN GUIDELINES FOR COMBAT AIRCRAFT c08
Marilyn E. Ogburn and John V. Foster *In its* NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 293-322 (For primary document see N94-25096 06-01)
Avail: CASI HC A03/MF A04

A broad research program to identify maneuvering requirements for advanced fighters and the corresponding design criteria to aid in making critical design tradeoffs is being conducted under the NASA High-Angle-of-Attack Technology Program (HATP). As part of this activity, NASA and the U.S. Navy are conducting cooperative research to develop high-angle-of-attack control margin requirements. This paper will summarize the status of this program. Following some background information, the simulation study conducted to develop a set of preliminary guidelines for nose-down pitch control is reviewed, and the results of some very limited flight tests are described. ROBUST, NONLINEAR, HIGH ANGLE-OF-ATTACK CONTROL DESIGN FOR A SUPERMANEUVERABLE VEHICLE c08
Richard J. Adams *In* NASA. Langley Research Center, NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 323-371 (For primary document see N94-25096 06-01)
Avail: CASI HC A03/MF A04

High angle-of-attack flight control laws are developed for a supermaneuverable fighter aircraft. The methods of dynamic inversion and structured singular value synthesis are combined into an approach which addresses both the nonlinearity and robustness problems of flight at extreme operating conditions. The primary purpose of the dynamic inversion control elements is to linearize the vehicle response across the flight envelope. Structured singular value synthesis is used to design a dynamic controller which provides robust tracking to pilot commands. The resulting control system achieves desired flying qualities and guarantees a large margin of robustness to uncertainties for high angle-of-attack flight conditions. The results of linear simulation and structured singular value stability analysis are presented to demonstrate satisfaction of the design criteria. High fidelity nonlinear simulation results show that the combined dynamics inversion/structured singular value synthesis control law achieves a high level of performance in a realistic environment. X-31 AERODYNAMIC CHARACTERISTICS DETERMINED FROM FLIGHT DATA c05
Alex Kokolios *In* NASA. Langley Research Center, NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 373-387 (For primary document see N94-25096 06-01)
Avail: CASI HC A03/MF A04

The lateral aerodynamic characteristics of the X-31 were determined at angles of attack ranging from 20 to 45 deg. Estimates of the lateral stability and control parameters were obtained by applying two parameter estimation techniques, linear regression, and the extended Kalman filter to flight test data. An attempt to apply maximum likelihood to extract parameters from the flight data was also made but failed for the reasons presented. An overview of the System Identification process is given. The overview includes a listing of the more important properties of all three estimation techniques that were applied to the data. A comparison is given of results obtained from flight test data and wind tunnel data for four important lateral parameters. Finally, future research to be conducted in this area is discussed. A STUDY OF ROLL ATTRACTOR AND WING ROCK OF DELTA WINGS AT HIGH ANGLES OF ATTACK c08
T. Niranjana, D. M. Rao, and Bandu N. Pamadi *In* NASA. Langley Research Center, NASA LaRC Workshop on Guidance, Navigation, Controls, and Dynamics for Atmospheric Flight, 1993 Dec. 1993 p 401-430 (For primary document see N94-25096 06-01)
Avail: CASI HC A03/MF A04

Wing rock is a high angle of attack dynamic phenomenon of limited cycle motion predominantly in roll. The wing rock is one of the limitations to combat effectiveness of the fighter aircraft. Roll Attractor is the steady state or equilibrium trim angle (phi(sub trim)) attained by the free-to-roll model, held at some angle of attack, and released form rest at a given initial roll (bank) angle (phi(sub O)). Multiple roll attractors are attained at different trim angles depending on initial roll angle. The test facility (Vigyan's low speed wind tunnel) and experimental work is presented here along with mathematical modelling of roll attractor phenomenon and analysis and comparison of predictions with experimental data. Avail: CASI HC A03/MF A04

The desire to achieve orbit-on-demand access to space with rapid turn-around capability and aircraft-like processing operations has given rise to numerous hypersonic aerospace plane design concepts which would take off horizontally from a conventional runway and employ air-breathing scramjet propulsion systems for acceleration to orbital speeds. Most of these air-breathing hypersonic vehicle concepts incorporate an elongated fuselage forebody to act as the aerodynamic compression surface for a scramjet combustor module. This type of airframe-integrated scramjet propulsion system tends to be highly sensitive to inlet conditions and angle-of-attack perturbations. Furthermore, the basic configuration of the fuselage, with its elongated and tapered forebody, produces relatively low frequency elastic modes which will cause perturbations in the combustor inlet conditions due to the oscillation of the forebody compression surface. The flexibility of the forebody compression surface, together with sensitivity of scramjet propulsion systems to inlet conditions, creates the potential for an unprecedented form of aeroelastic-propulsive interaction in which deflections of the vehicle fuselage give rise to propulsion transients, producing force and moment variations that may adversely impact the longitudinal flight dynamics and/or excite the elastic modes. These propulsive force and moment variations may have an appreciable impact on the performance, guidance, and control of a hypersonic aerospace plane. The objectives of this research are to quantify the magnitudes of propulsive force and moment perturbations resulting from elastic deformation of a representative hypersonic vehicle, and to assess the potential impact of these perturbations on the vehicle's longitudinal flight dynamics.

(Contract NCC2-583)
(NASA-CR-195198; NAS 1.26:195198) Avail: CASI HC A03/MF A01

The research conducted supported two facilities at NASA Ames Research Center: the Hypervelocity Free-Flight Aerodynamic Facility and the 16-Inch Shock Tunnel. During the grant period, a computerized film-reading system was developed, and five- and six-degree-of-freedom parameter-identification routines were written and successfully implemented. Studies of flow separation were conducted, and methods to extract phase shift information from finite-fringe interferograms were developed. Methods for constructing optical images from Computational Fluid Dynamics solutions were also developed, and these methods were used for one-to-one comparisons of experiment and computations. COMPUTATIONAL STUDY OF GA(W)-1: AIRFOIL NEAR STALL

J. Hoffren 1993 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-226249; SER-B-93-41) Avail: CASI HC A03

The testing of a new time-accurate thin-layer Navier-Stokes solver is continued with attempts to simulate the stall of the GA(W)-1 airfoil. Subsonic high Reynolds number flow at 7.0 - 19.5 degrees angle of attack is studied utilizing two different grids. Near the lower end of the angle of attack range, the results are reasonably good, but serious problems emerge as the stall proceeds. Unsteady solutions are obtained, although the time-averaged results agree poorly with measurements. The algebraic turbulence model applied is apparently inadequate for these types of time-dependent cases. The behavior of the solutions is also found to depend critically on the spatial resolution and the modeling of transition. The temporal accuracy may be an additional factor affecting the results. Since the calculations are very costly, it is not considered worthwhile to continue the effort with an improved resolution until a better, more physically sound turbulence model is available. NTIS

A NEW EXPERIMENTAL APPARATUS FOR THE STUDY OF THE UNSTEADY FLOWFIELD OVER AN AIRFOIL IN PITCHING AND HEAVING MOTIONS USING LASER DOPPLER ANEMOMETRY

P. Wernert, G. Koerber, and F. Wietrich 2 Oct. 1992 14 p Presented at the European Forum on Wind Tunnels and Wind Tunnel Test Techniques, Southampton, England, 14-17 Sep. 1992 See also A94-10438
(Contract DRET-86-156)
(ISL-CO-229/92; ETN-94-95126) Avail: CASI HC A03/MF A01

An experimental setup used for the study of the flowfield over an airfoil undergoing arbitrary pitching or heaving motions is described. This setup is basically composed of two parts: a novel driving mechanism, based on an automatic apparatus, two speed drives, two brushless motors and a support system, which allows the airfoil to be put into a wide range of periodic or transient motions and a classical two dimensional laser Doppler anemometry system which provides streamwise and transversal components of the velocity. Data acquisition, data reduction and synchronization problems are discussed. Results concerning dynamic stall features observed in the near wake of a pitching airfoil at a Reynolds number of 287,000 are given.

LDA MEASUREMENTS OF THE UNSTEADY NEAR WAKE BEHIND AN AIRFOIL UNDERGOING TRANSIENT AND PERIODIC PITCHING MOTIONS

P. Wernert, G. Koerber, and F. Wietrich 30 Jun. 1992 10 p Presented at the 6th International Symposium on Applications of Laser Techniques in Fluid Mechanics, Lisbon, Portugal, 20-23 Jul. 1992

(Contract DRET-86-156)
(ISL-CO-215/92; ETN-94-95124) Avail: CASI HC A02/MF A01

Results of two dimensional Laser Doppler Anemometry (LDA) measurements performed in the near wake of an airfoil undergoing stepwise motions and saw tooth periodic motions with incidence variations from -1 to 25 deg revealing dynamic stall features are presented. The driving mechanism used is based on an automatic apparatus which allows the airfoil to be put into a wide range of periodic or transient pitching and/or heaving motions. Time dependent velocity traces for the two components, streamwise velocity profiles, evolution of the semi-wake thickness, and vector velocity field are discussed. These results, obtained at a Reynolds number of 287,000, are compared to those corresponding to steady flow.

AN OVERVIEW OF A MODEL ROTOR ICING TEST IN THE NASA LEWIS ICING RESEARCH TUNNEL
Randall K. Britton (Sverdrup Technology, Inc., Brook Park, OH.), Thomas H. Bond, and Robert J. Flemming (Sikorsky Aircraft, Stratford, CT.) Jan. 1994 24 p Presented at the 32nd Aerospace Sciences Meeting, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(Contract NAS3-25266; RTOP 505-68-11)
(NASA-TM-106471; E-8340; NAS 1.15:106471; AIAA Paper 94-0716)
Avail: CASI HC A03/MF A01

During two entries in late 1989, a heavily instrumented sub-scale model of a helicopter main rotor was tested in the NASA LeRC Icing Research Tunnel (IRT). The results of this series of tunnel tests were published previously. After studying the results from the 1989 test and comparing them to predictions, it became clear that certain test conditions still needed investigation. Therefore, a re-entry of the Sikorsky Aircraft Powered Force Model (PFM) in the IRT was instituted in order to expand upon the current rotor craft sub-scale model experimental database. The major areas of interest included expansion of the test matrix to include a larger number of points in the FAA AC 29-2 icing envelope, inclusion of a number of high power rotor performance points, close examination of warm temperature operations, operation of the model in constant lift mode, and testing for conditions for icing test points in the full scale helicopter database. The expanded database will allow further and more detailed examination and comparison with analytical models. Participants in the test were NASA LeRC, the U.S. Army Vehicle Propulsion Directorate based at LeRC, and Sikorsky Aircraft. The model rotor was exposed to a range of icing conditions (temperature, liquid water content, median droplet diameter) and was operated over ranges of shaft angle, rotor tip speed, advance ratio, and rotor lift. The data taken included blade strain gage and balance data, as well as still photography, video, ice profile tracings, and ice molds. A discussion of the details of the test is given herein. Also, a brief examination of a subset of the data taken is also given. Author (revised)

MEASUREMENTS AND MODELING OF FLOW STRUCTURE IN THE WAKE OF A LOW PROFILE WISHBONE VORTEX GENERATOR
B. J. Wendt and W. R. Hingst Jan. 1994 11 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(RTOP 505-62-52)
(NASA-TM-106468; E-8334; NAS 1.15:106468; AIAA Paper 94-0620)
Avail: CASI HC A03/MF A01

The results of an experimental examination of the vortex structures shed from a low profile 'wishbone' generator are presented. The vortex generator height relative to the turbulent boundary layer was varied by testing two differently sized models. Measurements of the mean three-dimensional velocity field were conducted in cross-stream planes downstream of the vortex generators. In all cases, a counter-rotating vortex pair was observed. Individual vortices were characterized by three descriptors derived from the velocity data; circulation, peak vorticity, and cross-stream location of peak vorticity. Measurements in the cross plane at two axial locations behind the smaller wishbone characterize the downstream development of the vortex pairs. A single region of stream wise velocity deficit is shared by both vortex cores. This is in contrast to conventional generators, where each core coincides with a region of velocity deficit. The measured cross-stream velocities for each case are compared to an Oseen model with matching descriptors. The best comparison occurs with the data from the larger wishbone. Author (revised)

SIMPLIFIED, INVERSE, EJECTOR DESIGN TOOL
Lawrence J. DeChant Dec. 1993 37 p
(Contract NAS3-25266; RTOP 505-69-50)
(NASA-CR-194438; E-8289; NAS 1.26:194438) Avail: CASI HC A03/MF A01

A simple lumped parameter based inverse design tool has been developed which provides flow path geometry and entrainment estimates subject to operational, acoustic, and design constraints. These constraints are manifested through specification of primary mass flow rate or ejector thrust, fully-mixed exit velocity, and static pressure matching. Fundamentally, integral forms of the conservation equations coupled with the specified design constraints are combined to yield an easily invertible linear system in terms of the flow path cross-sectional areas. Entrainment is computed by back substitution. Initial comparison with experimental and analogous one-dimensional methods show good agreement. Thus, this simple inverse design code provides an analytically based, preliminary design tool with direct application to High Speed Civil Transport (HSCT) design studies.

LEADING-EDGE VOTEX-SYSTEM DETAILS OBTAINED ON F-106B AIRCRAFT USING A ROTATING VAPOR SCREEN AND SURFACE TECHNIQUES
John E. Lamar, Jay Brandon, Kathryn Stacy, Thomas D. Johnson, Jr. (Lockheed Engineering and Sciences Co., Hampton, VA.), Kurt Severance, and Brooks A. Childers Nov. 1993 159 p Original contains color illustrations
(RTOP 505-59-30-03)
(NASA-TP-3374; L-17150; NAS 1.60:3374) Avail: CASI HC A08/MF A02; 47 functional color pages

A flight research program to study the flow structure and separated-flow origins over an F-106B aircraft wing is described. The flight parameters presented include Mach numbers from 0.26 to 0.81, angles of attack from 8.5 deg to 22.5 deg, Reynolds numbers from 22.6 x 10(exp 6) to 57.3 x 10(exp 6) and load factors from 0.9 to 3.9 times the acceleration due to gravity. Techniques for vapor screens, image enhancement, photogrammetry, and computer graphics are integrated to analyze vortex-flow systems. Emphasis is placed on the development and application of the techniques. The spatial location of vortex cores and their tracks over the wing are derived from the analysis. Multiple vortices are observed and are likely attributed to small surface distortions in the wing leading-edge region. A major thrust is to correlate locations of reattachment lines obtained from the off-surface (vapor-screen) observations with those obtained from on-surface oil-flow patterns and pressure-port data. Applying vapor-screen image data to approximate reattachment lines is experimental, but depending on the angle of attack, the agreement with oil-flow results is generally good. Although surface pressure-port data are limited, the vapor-screen data indicate reattachment point occurrences consistent with the available data. Author (revised)

CHARACTERISTICS OF SURFACE ROUGHNESS ASSOCIATED WITH LEADING EDGE ICE ACCRETION
Jaiwon Shin Jan. 1994 18 p Presented at the AIAA 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(RTOP 505-68-10)
(NASA-TM-106459; E-8320; NAS 1.15:106459; AIAA Paper 94-0799)
Avail: CASI HC A03/MF A01

Detailed size measurements of surface roughness associated with leading edge ice accretions are presented to provide information on characteristics of roughness and trends of roughness development with various icing parameters. Data was obtained from icing tests conducted in the Icing Research Tunnel (IRT) at NASA Lewis Research Center (LeRC) using a NACA 0012 airfoil. Measurements include diameters, heights, and

spacing of roughness elements along with chordwise icing limits. Results confirm the existence of smooth and rough ice zones and that the boundary between the two zones (surface roughness transition region) moves upstream towards stagnation region with time. The height of roughness grows as the air temperature and the liquid water content increase, however, the airspeed has little effect on the roughness height. Results also show that the roughness in the surface roughness transition region grows during a very early stage of accretion but reaches a critical height and then remains fairly constant. Results also indicate that a uniformly distributed roughness model is only valid at a very initial stage of the ice accretion process.

LinAir: A MULTI-ELEMENT DISCRETE VORTEX WEISSINGER AERODYNAMIC PREDICTION METHOD

Donald A. Durston Oct. 1993 76 p Original contains color illustrations
(RTOP 505-59-20)
(NASA-TM-108786; A-93111; NAS 1.15:108786) Avail: CASI HC A05/MF A01; 1 functional color page

LinAir is a vortex lattice aerodynamic prediction method similar to Weissinger's extended lifting-line theory, except that the circulation around a wing is represented by discrete horseshoe vortices, not a continuous distribution of vorticity. The program calculates subsonic longitudinal and lateral/directional aerodynamic forces and moments for arbitrary aircraft geometries. It was originally written by Dr. Ilan Kroo of Stanford University, and subsequently modified by the author to simplify modeling of complex configurations. The Polhamus leading-edge suction analogy was added by the author to extend the range of applicability of LinAir to low aspect ratio (i.e., fighter-type) configurations. A brief discussion of the theory of LinAir is presented, and details on how to run the program are given along with some comparisons with experimental data to validate the code. Example input and output files are given in the appendices to aid in understanding the program and its use. This version of LinAir runs in the VAX/VMS, Cray UNICOS, and Silicon Graphics Iris workstation environments at the time of this writing. Author (revised)

EFFECT OF DELTA TABS ON MIXING AND AXIS SWITCHING IN JETS FROM ASYMMETRIC NOZZLES

K. B. M. Q. Zaman Jan. 1994 20 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(RTOP 537-02-22)
(NASA-TM-106450; E-8308; NAS 1.15:106450; AIAA Paper 94-0186)
Avail: CASI HC A03/MF A01

The effect of delta tabs on mixing and the phenomenon of axis switching in free air jets from various asymmetric nozzles was studied experimentally. Flow visualization and Pitot probe surveys were carried out with a set of small nozzles (D = 1.47 cm) at a jet Mach number, Mj = 1.63. Hot wire measurements for streamwise vorticity were carried out with larger nozzles (D = 6.35 cm) at Mj = 0.31. Jet mixing with the asymmetric nozzles, as indicated by the mass fluxes downstream, was found to be higher than that produced by a circular nozzle. The circular nozzle with four delta tabs, however, produced fluxes much higher than that produced by a asymmetric nozzles themselves or by most of the tab configurations tried with them. Even higher fluxes could be obtained with only a few cases, e.g., with 3:1 rectangular nozzle with two large delta tabs placed on the narrow edges. In this case, the jet 'fanned out' at a large angle after going through one axis switch. The axis switching could be either stopped or augmented with suitable choice of the tab configurations. Two mechanisms are identified governing the phenomenon. One, as described in Ref. 12 and referred to here as the omega(sub Theta)-induced dynamics, is due to differential induced velocities of different segments of a rolled up azimuthal vortical structure. The other is the omega(sub x)-induced dynamics due to the induced velocities of streamwise vortex pairs in the flow. While the former dynamics are responsible for rapid axis switching in periodically forced jets, the effect of the tabs is governed mainly by the latter. It is inferred that both dynamics are active in a natural asymmetric jet issuing from a nozzle having an upstream contraction. The tendency for axis switching caused by the omega(sub Theta)-induced dynamics is resisted by the omega(sub x)-induced dynamics, leading to a delayed or no switch over in that case. In jets from orifices and in screeching jets, the omega(sub Theta)-induced dynamics dominate causing a faster switch over. Author

(NASA-CR-194857; NAS 1.26:194857) Avail: CASI HC A03/MF A01

Nozzle design codes developed earlier under NAG1-1133 were modified and used in order to design a supersonic wind tunnel nozzle with square cross sections. As part of the design process, a computer code was written to implement the Hopkins and Hill perturbation solution for the flow in the transonic region of axisymmetric nozzles. This technique is used to design the bleed slot of quiet-flow nozzles. This new design code is documented in this report. Author

COMPRESSIBILITY EFFECTS ON DYNAMIC STALL OF AIRFOILS UNDERGOING RAPID TRANSIENT PITCHING MOTION Final Report, 1 Oct. 1989 - 30 Sep. 1992

M. S. Chandrasekhara (Naval Postgraduate School, Monterey, CA.) and M. F. Platzer (Naval Postgraduate School, Monterey, CA.) Nov. 1992 28 p
Sponsored in part by Naval Air Systems Command
(Grants AF-AFOSR-0012-90; AF-AFOSR-0007-91; AF-AFOSR-0004-92; AF Proj. 2307)
(NASA-TM-109681; NAS 1.15:109681) Avail: CASI HC A03/MF A01

The research was carried out in the Compressible Dynamic Stall Facility, CDSF, at the Fluid Mechanics Laboratory (FML) of NASA Ames Research Center. The facility can produce realistic nondimensional pitch rates experienced by fighter aircraft, which on model scale could be as high as 3600/sec. Nonintrusive optical techniques were used for the measurements. The highlight of the effort was the development of a new real time interferometry method known as Point Diffraction Interferometry - PDI, for use in unsteady separated flows. This can yield instantaneous flow density information (and hence pressure distributions in isentropic flows) over the airfoil. A key finding is that the dynamic stall vortex forms just as the airfoil leading edge separation bubble opens-up. A major result is the observation and quantification of multiple shocks over the airfoil near the leading edge. A quantitative analysis of the PDI images shows that pitching airfoils produce larger suction peaks than steady airfoils at the same Mach number prior to stall. The peak suction level reached just before stall develops is the same at all unsteady rates and decreases with increase in Mach number. The suction is lost once the dynamic stall vortex or vortical structure begins to convect. Based on the knowledge gained from this preliminary analysis of the data, efforts to control dynamic stall were initiated. The focus of this work was to arrive at a dynamically changing leading edge shape that produces only 'acceptable' airfoil pressure distributions over a large angle of attack range. Author

ISSAC, JASON CHERIAN SES IN TRANSONIC FLOW

Jason Cherion Issac and Rakesh K. Kapania [1993] 80 p
(Grant NAG1-1411)
(NASA-CR-194837; NAS 1.26:194837; VPI-AOE-210) Avail: CASI HC A05/MF A01

Flutter analysis of a two degree of freedom airfoil in compressible flow is performed using a state-space representation of the unsteady aerodynamic behavior. Indicial response functions are used to represent the normal force and moment response of the airfoil. The structural equations of motion of the airfoil with bending and torsional degrees of freedom are coupled to the unsteady air loads and the aeroelastic system so modelled is solved as an eigenvalue problem to determine the stability. The aeroelastic equations are also directly integrated with respect to time and the time-domain results compared with the results from the eigenanalysis. A good agreement is obtained. The derivatives of the flutter speed obtained from the eigenanalysis are calculated with respect to the mass and stiffness parameters by both analytical and finite-difference methods for various transonic Mach numbers. The experience gained from the two degree of freedom model is applied to study the sensitivity of the flutter response of a wing with respect to various shape parameters. The parameters being considered are as follows: (1) aspect ratio; (2) surface area of the wing; (3) taper ratio; and (4) sweep. The wing deflections are represented by Chebyshev polynomials. The compressible aerodynamic state-space model used for the airfoil section is extended to represent the unsteady aerodynamic forces on a generally laminated tapered skewed wing. The aeroelastic equations are solved as an eigenvalue problem to determine the flutter speed of the wing. The derivatives of the flutter speed with respect to the shape parameters are calculated by both analytical and finite difference methods. Author (revised)

(NASA-TM-106391; E-8216; NAS 1.15:106391; AIAA Paper 94-0582)

Avail: CASI HC A03/MF A01

Flows through a transonic diffuser were investigated with the PARC code using five turbulence models to determine the effects of turbulence model selection on flow prediction. Three of the turbulence models were algebraic models: Thomas (the standard algebraic turbulence model in PARC), Baldwin-Lomax, and Modified Mixing Length-Thomas (MMLT). The other two models were the low Reynolds number k-epsilon models of Chien and Speziale. Three diffuser flows, referred to as the no-shock, weak-shock, and strong-shock cases, were calculated with each model to conduct the evaluation. Pressure distributions, velocity profiles, locations of shocks, and maximum Mach numbers in the duct were the flow quantities compared. Overall, the Chien k-epsilon model was the most accurate of the five models when considering results obtained for all three cases. However, the MMLT model provided solutions as accurate as the Chien model for the no-shock and the weak-shock cases, at a substantially lower computational cost (measured in CPU time required to obtain converged solutions). The strong shock flow, which included a region of shock-induced flow separation, was only predicted well by the two k-epsilon models. Author (revised)

LIFT AUGMENTATION ON A DELTA WING VIA LEADING EDGE FENCES AND THE GURNEY FLAP M.S. Thesis

Mark D. Buchholz Dec. 1992 71 p

(Contract NCC2-730)

(NASA-CR-194793; NAS 1.26:194793) Avail: CASI HC A04/MF A01

Wind tunnel tests were conducted on two devices for the purpose of lift augmentation on a 60 deg delta wing at low speed. Lift, drag, pitching moment, and surface pressures were measured. Detailed flow visualization was also obtained. Both the leading edge fence and the Gurney flap are shown to increase lift. The fences and flap shift the lift curve as much as 5 deg and 10 deg, respectively. The fences aid in trapping vortices on the upper surface, thereby increasing suction. The Gurney flap improves circulation at the trailing edge. The individual influences of both devices are roughly additive, creating high lift gain. However, the lower lift to drag ratio and the precipitation of vortex burst caused by the fences, and the nose down pitching moment created by the flap are also significant factors. Author

A numerical method and a computer code were developed for the analysis of three dimensional (3D) airplane wing configurations in the subsonic regime. Comparisons with analytical solutions, experimental data, and commercial computer code validates the results. The overall approach is based on resolution of the Laplace equation. As is the case in any classical panel method, the linearity of the equation to be resolved allows limiting the problem to a surface integral. This linearity serves as a criterion of simplicity and will allow establishment of foundations for future developments in the 3D domain. The method is based directly on the full potential, which permits easy interpretation of the results. Using bi-linear doublet distributions only on triangular surface elements facilitates discretization of the configuration to be analyzed while limiting abrupt variations of the solution at the panel edges. To take into account the vorticity effects related to the lift developed on the wing, a wake relaxation is included which introduces a coupling approach into the calculation, since the shape of the wake is unknown at the start. A two dimensional semi-stationary development method is used to generate the wake behind the wing by convecting Treftz plans. Once the wake geometry is obtained, a new potential calculation is performed. Author (CISTI)

A radially constructed cruciform parachute is discussed. The parachute is adapted to support a load below it. The parachute itself includes a canopy having a hemispherically shaped member defining an apex in the uppermost portion. The canopy also defines a lower canopy edge that is generally circular around its lowermost portion. A plurality of panel members are each positioned extending vertically from a position adjacent the apex to the lower canopy edge. The panel members are attached with respect to one another along their vertically extending edges to form the hemispheric member of the canopy. Each panel includes upper and lower sections, and a plurality of the individual panels have lower panel sections which define open sections to form gores for facilitating stability of the overall parachute. These open sections extend from the lower canopy edge upwardly to the immediate edge of the upper panel and are defined laterally by the vertical edges of the adjacent panel sections. Each open section is positioned diametrically opposite another open section about the hemispheric member of the canopy to provide increased stability while inflating and after inflation. A plurality of support lines secured to the lower canopy edge extend downward to support the load. A preferred configuration of the parachute has 16 solid panels and eight panels with an open section. Author (CISTI)

REDUCTION OF STRUCTURAL LOADS USING MANEUVER LOAD CONTROL ON THE ADVANCED FIGHTER TECHNOLOGY INTEGRATION (AFTI)/F-111 MISSION ADAPTIVE WING

Stephen V. Thornton Washington Sep. 1993 31 p

(RTOP 505-63-50)

(NASA-TM-4526; H-1940; NAS 1.15:4526) Avail: CASI HC A03/MF A01

A transonic fighter-bomber aircraft, having a swept supercritical wing with smooth variable-camber flaps was fitted with a maneuver load control (MLC) system that implements a technique to reduce the inboard bending moments in the wing by shifting the spanwise load distribution inboard as load factor increases. The technique modifies the spanwise camber distribution by automatically commanding flap position as a function of flap position, true airspeed, Mach number, dynamic pressure, normal acceleration, and wing sweep position. Flight test structural loads data were obtained for loads in both the wing box and the wing root. Data from uniformly deflected flaps were compared with data from flaps in the MLC configuration where the outboard segment of three flap segments was deflected downward less than the two inboard segments. The changes in the shear loads in the forward wing spar and at the roots of the stabilators also are presented. The camber control system automatically reconfigures the flaps through varied flight conditions. Configurations having both moderate and full

trailing-edge flap deflection were tested. Flight test data were collected at Mach numbers of 0.6, 0.7, 0.8, and 0.9 and dynamic pressures of 300, 450, 600, and 800 lb/sq ft. The Reynolds numbers for these flight conditions ranged from 26 x 10(exp 6) to 54 x 10(exp 6) at the mean aerodynamic chord. Load factor increases of up to 1.0 g achieved with no increase in wing root bending moment with the MLC flap configuration.

An experimental study was conducted to determine the aerodynamic characteristics of a proposed high speed civil transport. This configuration was designed to cruise at Mach 3.0 and sized to carry 250 passengers for 6500 n.mi. The configuration consists of a highly blended wing body and features a blunt parabolic nose planform, a highly swept inboard wing panel, a moderately swept outboard wing panel, and a curved wingtip. Wind tunnel tests were conducted in the Langley Unitary Plan Wind Tunnel on a 0.0098-scale model. Force, moment, and pressure data were obtained for Mach numbers ranging from 1.6 to 3.6 and at angles of attack ranging from -4 to 10 deg. Extensive flow visualization studies (vapor screen and oil flow) were obtained in the experimental program. Both linear and advanced computational fluid dynamics (CFD) theoretical comparisons are shown to assess the ability to predict forces, moments, and pressures on configurations of this type. In addition, an extrapolation of the wind tunnel data, based on empirical principles, to full-scale conditions is compared with the theoretical aerodynamic predictions. Author (revised)

Three applications of the ethylene trace-gas technique to high-speed flows are described: flow-field tracking, air-to-air mixing, and bleed mass-flow measurement. The technique involves injecting a non-reacting gas (ethylene) into the flow field and measuring the concentration distribution in a downstream plane. From the distributions, information about flow development, mixing, and mass-flow rates can be dtermined. The trace-gas apparatus and special considerations for use in high-speed flow are discussed. A description of each application, including uncertainty estimates is followed by a demonstrative example. Author

(RTOP 505-68-70-08)
(NASA-TP-3358; L-17157; NAS 1.60:3358) Avail: CASI HC A05/MF A01

An experimental investigation was conducted to determine cavity flow-characteristics at subsonic and transonic speeds. A rectangular box cavity was tested in the Langley 8-Foot Transonic Pressure Tunnel at Mach numbers from 0.20 to 0.95 at a unit Reynolds number of approximately 3 x 10(exp 6) per foot. The boundary layer approaching the cavity was turbulent. Cavities were tested over a range of length-to-depth ratios (l/h) of 1 to 17.5 for cavity width-to-depth ratios of 1, 4, 8, and 16. Fluctuating- and static-pressure data in the cavity were obtained; however, only static-pressure data is analyzed. The boundaries between the flow regimes based on cavity length-to-depth ratio were determined. The change to transitional flow from open flow occurs at l/h at approximately 6-8 however, the change from transitional- to closed-cavity flow occurred over a wide range of l/h and was dependent on Mach number and cavity configuration. The change from closed to open flow as found to occur gradually. The effect of changing cavity dimensions showed that if the vlaue of l/h was kept fixed but the cavity width was decreased or cavity height was increased, the cavity pressure distribution tended more toward a more closed flow distribution. AERODYNAMIC CHARACTERISTICS AND PRESSURE DISTRIBUTIONS FOR AN EXECUTIVE-JET BASELINE AIRFOIL SECTION
Dennis O. Allison and Raymond E. Mineck Dec. 1993 103 p
(RTOP 505-59-10-30)
(NASA-TM-4529; L-17228; NAS 1.15:4529) Avail: CASI HC A06/MF A02

A wind tunnel test of an executive-jet baseline airfoil model was conducted in the adaptive-wall test section of the NASA Langley 0.3-Meter Transonic Cryogenic Tunnel. The primary goal of the test was to measure airfoil aerodynamic characteristics over a wide range of flow conditions that encompass two design points. The two design Mach numbers were 0.654 and 0.735 with corresponding Reynolds numbers of 4.5 x 10(exp 6) and 8.9 x 10(exp 6) based on chord, respectively, and normal-force coefficients of 0.98 and 0.51, respectively. The tests were conducted over a Mach number range from 0.250 to 0.780 and a chord Reynolds number range from 3 x 10(exp 6) to 18 x 10(exp 6). The angle of attack was varied from -2 deg to a maximum below 10 deg with one exception in which the maximum was 14 deg for a Mach number of 0.250 at a chord Reynolds number of 4.5 x 10(exp 6). Boundary-layer transition was fixed at 5 percent of chord on both the upper and lower surfaces of the model for most of the test. The adaptive-wall test section had flexible top and bottom walls and rigid sidewalls. Wall interference was minimized by the movement of the adaptive walls, and the airfoil aerodynamic characteristics were corrected for any residual top and bottom wall interference.

AN ANALYSIS FOR HIGH REYNOLDS NUMBER INVISCID/VISCID INTERACTIONS IN CASCADES Final Report
Mark Barnett, Joseph M. Verdon, and Timothy C. Ayer Washington May 1993 50 p
(Contract NAS3-25425; RTOP 584-03-11)
(NASA-CR-4519; E-7851; NAS 1.26:4519) Avail: CASI HC A03/MF A01

An efficient steady analysis for predicting strong inviscid/viscid interaction phenomena such as viscous-layer separation, shock/boundary-layer interaction, and trailing-edge/near-wake interaction in turbomachinery blade passages is needed as part of a comprehensive analytical blade design prediction system. Such an analysis is described. It uses an inviscid/viscid interaction approach, in which the flow in the outer inviscid region is assumed to be potential, and that in the inner or viscous-layer region is governed by Prandtl's equations. The inviscid solution is determined using an implicit, least-squares, finite-difference approximation, the viscous-layer solution using an inverse, finite-difference, space-marching method which is applied along the blade surfaces and wake streamlines. The inviscid and viscid solutions are coupled using a semi-inverse global iteration procedure, which permits the prediction of boundary-layer separation and other strong-interaction phenomena. Results are presented for three cascades, with a range of inlet flow conditions considered for one of them, including conditions leading to large-scale flow separations. Comparisons with Navier-Stokes solutions and experimental data are also given. Author (revised)

The circular body configuration is a generic single- or multi-stage reusable Earth-to-orbit transport. A thick clipped-delta wing is the major lifting surface. For directional control, three different vertical fin arrangements were investigated: a conventional aft-mounted center fin, wingtip fins, and a nose-mounted fin. The tests were conducted in the Langley Unitary Plan Wind Tunnel. The configuration is longitudinally stable about the estimated center of gravity of 0.72 body length up to a Mach number of about 3.0. Above Mach 3.0, the model is longitudinally unstable at low angles of attack but has a stable secondary trim point at angles of attack above 30 deg. The model has sufficient pitch control authority with elevator and body flap to produce stable trim over the test range. The model with the center fin is directionally stable at low angles of attack up to a Mach number of 3.90. The rudder-like surfaces on the tip fins and the all-movable nose fin are designed as active controls to produce artificial directional stability and are effective in producing yawing moment. The wing trailing-edge aileron surfaces are effective in producing rolling moment, but they also produce large adverse yawing moment. Author (revised)

NONLINEAR EQUATIONS OF MOTION FOR A PANEL SUBJECT TO EXTERNAL LOADS Interim Report, Jan. 1992 - Oct. 1993

Mark A. Hopkins Nov. 1993 45 p
(AF Proj. 2401)
(AD-A273142; WL-TM-93-308) Avail: CASI HC A03/MF A01

The equations of motion of a constant thickness, rectangular panel subject to external static loads and unsteady supersonic aerodynamic forces is derived. Both isotropic and orthotropic panels are examined. The static loads come from in-plane forces, a temperature differential, and a pressure differential. The equations allow for slight initial curvature due to manufacturing imperfections. The equations are derived using a nonlinear strain-displacement relationship which permits both linear and nonlinear panel response studies. First order piston theory predicts the unsteady aerodynamic forces due to the supersonic flow over the upper surface. DTIC

NUMERICAL FLOW SIMULATION FOR COMPLETE VEHICLE CONFIGURATIONS Final Report, 1 Apr. 1990 - 31 Mar. 1993

Bharat K. Soni 1 Sep. 1993 74 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-90-C-0027)
(AD-A273588; AFOSR-93-0863TR) Avail: CASI HC A04

In the spirit of the Air Force Office of Scientific Research's (AFOSR) initiative to promote university/industry collaborative research, a collaborative project entitled, Numerical Flow Simulation for Complete Vehicle Configurations has been executed by the National Science Foundation Engineering Research Center for Computational Field Simulation (NSF ERC) at Mississippi State University. The industrial participants include McDonnell Aircraft Company, McDonnell Douglas Research and Development Company, and Teledyne Brown Engineering Company. The research and development activities of this effort are focused on the advancement of methodologies to increase the efficiency, quality, and productivity of an overall CFD simulation associated with geometrically complex configurations. The progress realized in the aforestated development is presented in this report. Progress concerning efforts designed to increase the efficiency and productivity of an overall CFD simulation process--from geometry definition to post processing of results as applied to complete aircraft configurations--is presented. This progress has been brought about through enhancements in geometry processing, surface grid generation, grid refinement, grid adaptation, and domain decomposition strategies. DTIC

REGULATED DRAG AREA PARACHUTE Patent

Elsa J. Hennings, inventor (to Navy) 28 Sep. 1993 11 p Filed 8 Apr. 1992
(AD-D015992; US-Patent-5,248,117; US-Patent-Appl-SN-866649; US-Patent-Class-244-152) Avail: US Patent and Trademark Office

The disclosed invention is a regulated drag area parachute for decelerating a manned ejection seat or an ejectable capsule at a low altitude from an aircraft or other air vehicle. This parachute comprises a canopy composed of two portions, suspension lines, and a means for controlling the inflation of the canopy so that the two portions of the canopy inflate independently from one another. This means for controlling the inflation of the canopy provides a manner to regulate the rate of infraction of the lower portion of the canopy. Thus, the invention allows the top, or apex portion of the canopy, to inflate rapidly while the remaining portion of the canopy can be inflated subsequently and in a controlled manner so that the effective drag area of the canopy can be regulated during the deployment of the parachute. SUB-SONIC FLOW ABOUT A SLENDER PROFILE IN A TUNNEL HAVING PERFORATED WALLS [DOZVUKOVOE OBTEKANIE TONKOGO PROFILYA V KANALE S PERFORIROVANNYMI STENKAMI]

S. A. Glaskov 8 Feb. 1993 16 p Transl. into ENGLISH from Uchenye Zapiski Tsagi (Russia), v. 22, no. 2, 1991 p 3-12
(AD-A273184; DRA-Library-Trans-2202) Avail: CASI HC A03/MF A01

A solution has been found for the problem of flow about a profile by an ideal incompressible liquid in a tunnel, the upper and lower walls of which may have varying porosity, depending on whether gas flows in or out of the tunnel. Calculations have been made of the distributions of pressure on the walls of the tunnel and on the profile located at an angle of attack on the axis of symmetry of the tunnel. DTIC

ANALYTICAL SKIN FRICTION AND HEAT TRANSFER FORMULA FOR COMPRESSIBLE INTERNAL FLOWS Final Report

Lawrence J. DeChant and Marc J. Tattar (Ohio Aerospace Inst., Brook Park.) Jan. 1994 20 p
(Contract NAS3-25266; RTOP 505-69-50)
(NASA-CR-191185; E-8096; NAS 1.26:191185) Avail: CASI HC A03/MF A01

An analytic, closed-form friction formula for turbulent, internal, compressible, fully developed flow was derived by extending the incompressible law-of-the-wall relation to compressible cases. The model is capable of analyzing heat transfer as a function of constant surface temperatures and surface roughness as well as analyzing adiabatic conditions. The formula reduces to Prandtl's law of friction for adiabatic, smooth, axisymmetric flow. In addition, the formula reduces to the Colebrook equation for incompressible, adiabatic, axisymmetric flow with various roughnesses. Comparisons with available experiments show that the model averages roughly 12.5 percent error for adiabatic flow and 18.5 percent error for flow involving heat transfer. Author (revised)

IMPROVING DIFFUSING S-DUCT PERFORMANCE BY SECONDARY FLOW CONTROL

Bruce A. Reichert and Bruce J. Wendt Feb. 1994 12 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(RTOP 505-62-52)
(NASA-TM-106492; E-8479; NAS 1.15:106492; AIAA Paper 94-0365)
Avail: CASI HC A03/MF A01

The objective of this research was to study ways to reduce inlet flow distortion (i.e., total pressure nonuniformity) and improve total pressure recovery in a diffusing S-duct. This was accomplished by controlling the development of secondary flows within the duct through the use of tapered-fin type vortex generators. Reported are results for the bare duct and seven different configurations of vortex generators. Data presented for each configuration include surface static pressure, surface flow visualization, and exit plane total pressure and transverse velocity. The performance of each configuration was assessed by calculating total pressure recovery and inlet distortion descriptors from the data and comparing them to the values for the bare duct. The best configuration tested reduced distortion (as measured by the DC(45) and DC(90) descriptors) by more than 50 percent while improving total pressure recovery by 0.5 percent. These results should provide valuable guidance in designing vortex generator installations in ducts and for assessing the accuracy of computational fluid dynamics (CFD) methods to calculate duct flows with installed vortex generators. EFFECT OF AN EXTENDABLE SLAT ON THE STALL BEHAVIOR OF A VR-12 AIRFOIL

P. Plantin DeHugues (Ministere des Affaires Etrangeres, Paris, France.), K. W. McAlister (Army Aviation Systems Command, Moffett Field, CA.), and C. Tung (Army Aviation Systems Command, Moffett Field, CA.) Sep. 1993 65 p

(RTOP 505-61-51)

(NASA-TP-3407; A-93056; NAS 1.60:3407; ATCOM-TR-93-A-002) Avail: CASI HC A04/MF A01

Experimental and computational tests were performed on a VR-12 airfoil to determine if the dynamic-stall behavior that normally accompanies high-angle pitch oscillations could be modified by segmenting the forward portion of the airfoil and extending it ahead of the main element. In the extended position the configuration would appear as an airfoil with a leading-edge slat, and in the retracted position it would appear as a conventional VR-12 airfoil. The calculations were obtained from a numerical code that models the vorticity transport equation for an incompressible fluid. These results were compared with test data from the water tunnel facility of the Aeroflightdynamics Directorate at Ames Research Center. Steady and unsteady flows around both airfoils were examined at angles of attack between 0 and 30 deg. The Reynolds number was fixed at 200,000 and the unsteady pitch oscillations followed a sinusoidal motion described by alpha = alpha(sub m) + 10 deg sin(omega t). The mean angle (alpha(sub m)) was varied from 10 to 20 deg and the reduced frequency from 0.05 to 0.20. The results from the experiment and the calculations show that the extended-slat VR-12 airfoil experiences a delay in both static and dynamic stall not experienced by the basic VR-12 airfoil. Author

STATE-OF-THE-ART ENGINEERING AEROPREDICTION METHODS WITH EMPHASIS ON NEW SEMIEMPIRICAL TECHNIQUES FOR PREDICTING NONLINEAR AERODYNAMICS ON COMPLETE MISSILE CONFIGURATIONS Final Report

Frank G. Moore Nov. 1993 165 p

(AD-A273680; NSWCDD/TR-93/551) Avail: CASI HC A08/MF A02

The pros and cons of numerical, semiempirical, and empirical aeroprediction codes are discussed and many state-of-the-art codes in use today are listed. It then summarizes many of the more popular approximate analytical methods used in State-of-the-Art (SOTA) semiempirical aeroprediction codes. It also summarizes some recent new nonlinear semiempirical methods that allow more accurate calculation of static aerodynamics on complete missile configurations to higher angles of attack. Results of static aerodynamic calculations on complete missile configurations compared to wind tunnel data are shown for several configurations at various flight conditions. Calculations show the new nonlinear methods being far superior to some of the former linear technology when used at angles of attack greater than about 15 degrees. DTIC

DETAILED DESCRIPTION OF TWO CALCULATION PROGRAMS FOR INCOMPRESSIBLE, STEADY STATE BOUNDARY LAYER FLOWS, APPLIED TO DETERMINE THE AERODYNAMIC CHARACTERISTICS OF NACA12 AND OA312 FOILS AT LOW REYNOLDS NUMBERS [DESCRIPTION DETAILLEE DE DEUX PROGRAMMES DE CALCUL DE COUCHE LIMITE STATIONNAIRE, INCOMPRESSIBLE, UTILISES POUR LA DETERMINATION DES CARACTERISTIQUES AERODYNAMIQUES DES PROFILS NACA12 ET OA312 A FAIBLE NOMBRE DE REYNOLDS]

P. Wernert 29 Apr. 1992 37 p In FRENCH

(ISL-N-604/92; ETN-94-95117) Avail: CASI HC A03/MF A01

In the scope of the study concerning unsteady flows due to oscillating foils, the steady pressure field was measured. Boundary layer computer programs were applied to calculate C(sub x), C(sub z), and C(sub m) coefficients. The two programs used for calculating boundary layer characteristics of oscillating foils in incompressible flows were CLTHA1 and THDIM. Both programs are based on the Thwaites integral method for laminar flows. The turbulent boundary layer is calculated with CLTHA1 by applying a Lazareff-Semezis modified integration method and with THDIM by the Head method. The block diagrams of both programs are included. ANALYSIS AND CHARACTERISTICS OF COMPRESSOR STALL PRECURSOR SIGNALS IN FORWARD AND AFT SWEPT HIGH SPEED COMPRESSOR M.S. Thesis

Bernard J. Frank Dec. 1993 127 p

(AD-A273820; AFIT/GAE/ENY/93D-14) Avail: CASI HC A07/MF A02

The stall characteristics of four single-stage transonic compressor rotors were investigated as they were throttled to stall. Forward-swept, backward-swept, and straight leading edge rotors were examined. Three methods of analysis--windowed power spectrum densities of pressure and spatial Fourier coefficients, phase tracking analysis, and system identification--were used to identify the first appearance of modal waves and their accompanying frequencies in order to identify a stall warning time. A direct correlation between the amount of stall warning time and the shape of the compressor characteristic was found. Specifically, if the compressor characteristic had a significant period of flat or positive slope, more stall warning was noted. It was also found that the forward-swept rotor consistently provided more stall warning time than the backward-swept and straight leading edge rotors. DTIC

AIRPORT SURFACE OPERATIONS REQUIREMENTS ANALYSIS Final Report
John L. Groce, Greg J. VonBokern, and Rick L. Wray Aug. 1993 101 p
(Contract NAS1-18027; RTOP 505-64-13-01)
(NASA-CR-191508; NAS 1.26:191508) Avail: CASI HC A06/MF A02

This report documents the results of the Airport Surface Operations Requirements Analysis (ASORA) study. This study was conducted in response to task 24 of NASA Contract NAS1-18027. This study is part of NASA LaRC's Low Visibility Surface Operations program, which is designed to eliminate the constraints on all-weather arrival/departure operations due to the airport/aircraft ground system. The goal of this program is to provide the capability for safe and efficient aircraft operations on the airport surface during low visibility conditions down to zero. The ASORA study objectives were to (1) develop requirements for operation on the airport surface in visibilities down to zero; (2) survey and evaluate likely technologies; (3) develop candidate concepts to meet the requirements; and (4) select the most suitable concept based on cost/benefit factors. CLOSE-UP ANALYSIS OF INFLIGHT ICE ACCRETION
Andrew L. Reehorst, Thomas P. Ratvasky, and James Sims (Cortez 3 Services Corp., Brook Park, OH.) Jan. 1994 12 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(Contract NAS3-24816; RTOP 505-68-10)
(NASA-TM-106457; E-8318; NAS 1.15:106457; AIAA Paper 94-0804)
Avail: CASI HC A03/MF A01

The objective of this effort was to validate in flight, data that has been gathered in the NASA Lewis Research Center's Icing Research Tunnel (IRT) over the past several years. All data was acquired in flight on the NASA Lewis Research Center's Twin Otter Icing Research Aircraft. A faired 3.5 in. diameter metal-clad cylinder exposed to the natural icing environment was observed by a close-up video camera. The grazing angle video footage was recorded to S-VHS video tape and after the icing encounter, the resultant ice shape was documented by 35 mm photography and pencil tracings. The feather growth area was of primary interest; however, all regions of the ice accretion, from the stagnation line to the aft edge of run back were observed and recorded. After analysis of the recorded data several interesting points became evident: (1) the measured flight feather growth rate is consistent with IRT values, (2) the feather growth rate appears to be influenced by droplet size, (3) the feathers were straighter in the lower, spottier LWC of flight in comparison to those observed in the IRT, (4) feather shedding and ice sublimation may be significant to the final ice shape, and (5) the snow encountered on these flights appeared to have little influence on ice growth. AIRCRAFT ACCIDENT REPORT: INADVERTENT IN-FLIGHT SLAT DEPLOYMENT, CHINA EASTERN AIRLINES FLIGHT 583, MCDONNELL DOUGLAS MD-11, B-2171, 950 NAUTICAL MILES SOUTH OF SHEMYA, ALASKA, 6 APRIL 1993
27 Oct. 1993 73 p
(PB93-910408; NTSB/AAR-93/07) Avail: CASI HC A04/MF A01

This report explains the inadvertent deployment of the MD-11 airplane's leading edge wing slats while the airplane was in cruise flight, about 950 nautical miles south of Shemya, Alaska, on April 6, 1993. Safety issues in the report focused on the inadequate design of the flap/slat actuation handle, the inadvertent extension of the leading edge wing slats, the longitudinal stability of the airplane during the pitch upset, the pilot-induced oscillations that can occur during recovery, the premature deterioration of the seat cushion fire-blocking material, and the inability of the material to provide the required seat cushion fire protection on transport-category airplanes. Safety recommendations on these issues were made to the Federal Aviation Administration. Author

DISPERSION OF FIRE SUPPRESSION AGENTS DISCHARGED FROM HIGH PRESSURE VESSELS: ESTABLISHING INITIAL/BOUNDARY CONDITIONS FOR THE FLOW OUTSIDE THE VESSEL
L. Y. Cooper Sep. 1993 38 p Sponsored by Department of the Air Force, Wright-Patterson AFB, OH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-103660; NISTIR-5219) Avail: Issuing Activity (National Technical Information Service (NTIS))

The dispersion and extinguishment effectiveness of Halon and Halon-alternative fire extinguishment agents discharged from N2-pressurized vessels was studied. In the systems under consideration, as the agent exists from the vessel, thermodynamic and fluid-dynamic instabilities lead to flashing and break-up of the agent into a two-phase droplet/gaseous jet mixture. This occurs in a transition region relatively close to the vessel exit orifice/nozzle. Downstream of this region the two-phase agent jet then mixes with the ambient air environment and is dispersed in the protected space. A mathematical model was developed previously to simulate the time-dependent discharge of the agent from the pressure vessel. Using the output of this model and thermodynamic and fluid-dynamic considerations of the phenomena in the transition section, the present work develops a method for determining a set of initial/boundary conditions at an initial section of the jet, downstream of the transition region. These initial/boundary conditions are in a form that can be used to formulate and solve the problem of the development and dispersal of the ensuing mixed air/two-phase-agent jet. Example applications of the developed methodology are presented. These are for agent discharge from a half-liter cylindrical discharge vessel with a circular discharge nozzle/orifice of diameter 0.019m. Simulations involve discharge of the vessel when it is half-filled with either Freon 22 or Halon 1301 and then pressurized with N2 to 41.37 x 10(exp 5)Pa (600psi). NTIS

RIME-, MIXED- AND GLAZE-ICE EVALUATIONS OF THREE SCALING LAWS

David N. Anderson Jan. 1994 15 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(RTOP 505-68-10)
(NASA-TM-106461; E-8323; NAS 1.15:106461; AIAA Paper 94-0718)
Avail: CASI HC A03/MF A01

This report presents the results of tests at NASA Lewis to evaluate three icing scaling relationships or 'laws' for an unheated model. The laws were LWC x time = constant, one proposed by a Swedish-Russian group and one used at ONERA in France. Icing tests were performed in the NASA Lewis Icing Research Tunnel (IRT) with cylinders ranging from 2.5- to 15.2-cm diameter. Reference conditions were chosen to provide rime, mixed and glaze ice. Scaled conditions were tested for several scenarios of size and velocity scaling, and the resulting ice shapes compared. For rime-ice conditions, all three of the scaling laws provided scaled ice shapes which closely matched reference ice shapes. For mixed ice and for glaze ice none of the scaling laws produced consistently good simulation of the reference ice shapes. Explanations for the observed results are proposed, and scaling issues requiring further study are identified. Author

A NUMERICAL STUDY OF AIRPLANES FLYING IN PROXIMITY M.S. Thesis

David B. Porter Sep. 1993 140 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273373) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

During an emergency such as an unsafe landing gear indication, a second aircraft is often used to perform an airborne visual inspection of the landing gear. The chase airplane may be quite dissimilar in size and wing loading and consequently experience unexpected aerodynamic forces and moments caused by the other airplane. A numerical study of the inherent danger involved with the aerodynamic interaction of aircraft flying in proximity was made using the low-order panel code PMARC (Panel Method Ames Research Center). PMARC validation was made by comparing wind tunnel and analytically derived stability data for T-34 and F-14 models with PMARC results. A T-34 was then placed at various distances underneath an F-14 to determine changes in lift and pitching moments on the T-34. Color illustrations of pressure coefficients were used to highlight the changes in aerodynamic forces and moments as vertical separation between the two aircraft was decreased. PMARC showed that 4.5 degrees of elevator trim change was required as a T-34 approached to within its semispan of an F-14. DTIC

INFORMATION SYSTEMS STRATEGY IN AIR TRANSPORT M.S. Thesis

Desmond P. McGlade Sep. 1993 135 p
(AD-A273125) Avail: CASI HC A07/MF A02

Seeking to improve the role of Information Technology (IT) and business practices in the Department of Defense, organizations were sought to serve as a model to aid in the improvement process. Southwest Airlines, a major U.S. carrier based in Dallas, Texas was chosen because of its record of profitability and its unique use of information technology. This case study describes Southwest's mission, goals, organization, business decisions, attitude, growth and information technology. The primary focus is the fact that Southwest does not participate in a major carrier's reservation system. Lessons learned for a military officer in terms of Information Technology are to avoid redundancy, improve functionality, avoid expensive enhancements that do not contribute to our requirements, and don't discount old technologies. DTIC

ANNUAL REVIEW OF AIRCRAFT ACCIDENT DATA. US GENERAL AVIATION CALENDAR YEAR 1990

17 Dec. 1993 83 p
(PB94-126869; NTSB/ARG-93/02) Avail: CASI HC A05/MF A01

This report presents a statistical compilation and review of general aviation accidents which occurred in 1990 in the United States, its territories and possessions, and in international waters. The accidents reported are all those involving U.S. registered aircraft not conducting operations under 14 CFR 121, 14 CFR 125, 14 CFR 127, or 14 CFR 135. This report is divided into five actions: all accidents, fatal accidents, serious injury accidents, property damage accidents, and midair collision accidents. Several tables present accident parameters for 1990 accidents only, and each section includes tabulations which present comparative statistics for 1990 and for the five-year period 1985-1989. AVIATION SYSTEM SAFETY RISK MANAGEMENT TOOL ANALYSIS. VOLUME 2: APPENDICES Final Report

D. C. Thill and D. B. Hammilton Oct. 1993 372 p

(Contract MDA903-92-D-0025)
(AD-A273502; ARL-CR-120-Vol-2) Avail: CASI HC A16/MF A03

U.S. Army risk management is a process used to minimize loss of life, injuries, and property damage. One step in the risk management process is risk assessment. Currently, risk assessment assigns a probability value for an identified hazard, based on a subjective evaluation. The need exists to assign objective probability values when assessing the risks imposed by aircraft component and part failures. This research extracted UH-60 and UH-1 helicopter part failure data for a ten-year period from the Army Safety Management Information System (ASMIS) data base. Data inconsistencies were corrected, the corrected data were organized into groups, and failure rates were calculated. The results established that component and part failure analyses can be successfully conducted using available data bases and that these data can be used to quantify hazard probabilities for failed aircraft components and parts. Volume one of this report describes the methodology used to obtain the failure rates, presents the results of the analyses, discusses potential uses for the data, and provides recommendations for further research. Volume two provides a table of part failure rates and a list of records for the UH-60 (see Appendix A) and for the UH-1 (see Appendix B). DTIC

FULL-SCALE FIRE TESTING OF SEAT COMPONENT MATERIALS
Patricia Gahill Oct. 1993 26 p
(AD-A273499; DOT/FAA/CT-TN93/13) Avail: CASI HC A03/MF A01

Full-scale fire testing was conducted in a furnished aircraft cabin to compare a currently used thermoplastic material and a new thermoplastic material with low heat and smoke release characteristics used in forming seat components. This testing was conducted due to questions concerning the exemption of seat components from the heat release and smoke requirement mandated for certain large surface area components in the aircraft fuselage. Results of the fullscale testing showed no significant difference in temperatures, smoke levels, or oxygen depletion between the two materials. While carbon monoxide and carbon dioxide emissions were slightly higher with the currently used material, it cannot be concluded that this material was the cause. Based on the overall data, it appears that the small amount of seat component material is not significantly contributing to increased fire hazards. DTIC

PROJECTED EFFECTIVENESS OF AIRBAG SUPPLEMENTAL RESTRAINT SYSTEMS IN US ARMY HELICOPTER COCKPITS Final Report
Dennis F. Shanahan, Samuel G. Shannon, and James E. Bruckart Sep. 1993 27 p
(DA Proj. 3M1-62787-A-878)
(AD-A273250) Avail: CASI HC A03/MF A01

Despite significant advances in accident prevention, crashworthiness, and individual protective equipment, head and torso injuries continue to cause death and disabling injuries in survivable Army helicopter accidents. Most of these injuries are caused by the occupant striking internal structures. The purpose of this study was to review Army helicopter accident records to determine the number of fatal and disabling injuries in pilots and copilots that could be prevented with the introduction of an airbag supplemental restraint system into U.S. Army helicopter cockpits. AIRCRAFT ACCIDENT REPORT: IN-FLIGHT LOSS OF PROPELLER BLADE AND UNCONTROLLED COLLISION WITH TERRAIN MITSUBISHI MU-2B-60, N86SD, ZWINGLE, IOWA, 19 APRIL 1993
16 Nov. 1993 130 p
(PB93-910409; NTSB/AAR-93/08) Avail: CASI HC A07/MF A02

The in-flight loss of propellar blade and subsequent crash of an Mu-2B-60 airplane, operated by the South Dakota Department of Transportation, while the flightcrew was attempting an approach to an emergency landing at Dubuque Regional Airport, Dubuque, Iowa, on 19 April 1993 is explained. The safety issues discussed include the propeller hub design, certification and continuing airworthiness, and air traffic control training. Recommendations concerning these issues were made to the Federal Aviation Administration. Author (revised)

CONFLICT-FREE TRAJECTORY PLANNING FOR AIR TRAFFIC CONTROL AUTOMATION
Rhonda Slattery and Steve Green Jan. 1994 19 p Original contains color illustrations
(RTOP 505-64-13)
(NASA-TM-108790; A-93132; NAS 1.15:108790) Avail: CASI HC A03/MF A01; 6 functional color pages

As the traffic demand continues to grow within the National Airspace System (NAS), the need for long-range planning (30 minutes plus) of arrival traffic increases greatly. Research into air traffic control (ATC) automation at ARC has led to the development of the Center-TRACON Automation System (CTAS). CTAS determines optimum landing schedules for arrival traffic and assists controllers in meeting those schedules safely and efficiently. One crucial element in the development of CTAS is the capability to perform long-range (20 minutes) and short-range (5 minutes) conflict prediction and resolution once landing schedules are determined. The determination of conflict-free trajectories within the Center airspace is particularly difficult because of large variations in speed and altitude. The paper describes the current design and implementation of the conflict prediction and resolution tools used to generate CTAS advisories in Center airspace. Conflict criteria (separation requirements) are defined and the process of separation prediction is described. The major portion of the paper will describe the current implementation of CTAS conflict resolution algorithms in terms of the degrees of freedom for resolutions as well as resolution search techniques. The tools described in this paper have been implemented in a research system designed to rapidly develop and evaluate prototype concepts and will form the basis for an operational ATC automation system. AN OVERVIEW OF A GENERIC MULTI-SENSOR INTEGRATED NAVIGATION SYSTEM DESIGN
D. F. Liang Jun. 1993 22 p

(CTN-94-60916) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

The application of Kalman filtering technology to the design and development of a multi-sensor generic integrated navigation system (GINS) for aircraft is described. The primary system component is the integrated sensor unit which consists of all the selected navigation sensors. These sensors can be classified into two main categories: dead reckoning (DR) and radio navigation systems. To take advantage of the short-term stability of the DR system and the long-term stability of the radio navigation system, optimal estimation theory can be applied in the form of a Kalman filter (KF) to combine all the available measurements and provide a statistically optimal estimate of aircraft position and other parameters. To achieve the desired performance, the GINS processor must perform signal conditioning and sensor compensation functions and must contain efficient KF integration algorithms, error control, and performance monitoring routines. The system development approach is described, as well as system error modelling, and KF design. CISTI

ANALYSIS AND SURVEILLANCE PERFORMANCE AT CHICAGO O'HARE AIRPORT Project Report
Sylvia I. Altman, Douglas W. Burgess, Richard G. Potts, Ronald G. Sandholm, and M. Loren Wood 28 Jan. 1994 95 p
(Contracts DTFA-01-93-Z-02018; F19628-90-C-0002)
(DOT/FAA/RD-92/29; ATC-193) Avail: CASI HC A05/MF A01

The results of RF measurements of the 1030 and 1090 MHz environment in the Chicago terminal area conducted by Lincoln Laboratory in October 1991 are described. The measurements were made at the request of the FAA in response to reports by controllers in Chicago that TCAS interrogations are affecting the surveillance performance of the Chicago Secondary Surveillance Radar (SSR). The Airborne Measurements Facility (AM), developed at Lincoln Laboratory, was used to gather TCAS and SSR interrogation and reply data in the vicinity of O'Hare Airport during periods of active TCAS operation. Simultaneously, local aircraft track data were collected using the Automated Radar Terminal System (ARTS) data recording facility. Analysis of both the AMF data and the ARTS data show that TCAS interrogations do not cause a significant degradation in SSR surveillance performance and that the average Chicago ARTS track performance in the presence of TCAS-equipped aircraft is comparable to earlier measurements of track performance in Chicago as well as at a number of other high-density terminal areas. Specific regions within the Chicago surveillance area were observed to contain concentrations of poor ARTS track performance, and analysis of the data has shown the cause to be differential vertical lobing associated with the SSR antenna and faulty Mode S transponders on certain air carrier aircraft. Both of these problems were subsequently corrected. Author (revised)

AN INVESTIGATION INTO ACCELERATION DETERMINATION FOR AIRBORNE GRAVIMETRY USING THE GLOBAL POSITIONING SYSTEM M.S. Thesis
Derrick R. Peyton Jun. 1990 155 p
(ISBN-0-315-59470-5; CTN-94-60873) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305 Ottawa, Ontario, K2P 2G8, Canada HC/MF

The determination of acceleration using the NAVSTAR Global Positioning System (GPS) is investigated for airborne gravimetric applications. The position and velocity requirements for airborne gravimetry were met using GPS observing and processing techniques. However, the separation of the aircraft acceleration from the observed gravity still remains to be resolved to the 1-2 milligal accuracy requirements. As a means to move toward achieving such accuracy, a model is developed in which the accelerations are obtained by utilizing the second time derivative of the GPS carrier phase. Carrier phase data were collected from pairs of GPS receivers located at fixed points. Spectral analysis techniques for determining acquired acceleration accuracy were applied to computed accelerations from these data sets. Low-pass filters were applied to the acceleration data to separate the high frequency receiver measurement noise from the low frequency acceleration data. The implications and handling of GPS data contaminated by selective availability are addressed. Results show that for carrier phase observations over a fixed baseline of under 100 m, differential techniques can give accelerations which meet the 1-2 milligal accuracy requirements. AN EXAMINATION OF THE OPERATIONAL ERROR DATABASE FOR AIR ROUTE TRAFFIC CONTROL CENTERS Final Report
Mark D. Rodgers, ed. Dec. 1993 29 p
(DOT/FAA/AM-93/22) Avail: CASI HC A03/MF A01

Monitoring the frequency and determining the causes of operational errors - defined as the loss of prescribed separation between aircraft - is one approach to assessing the operational safety of the air traffic control system. The Federal Aviation Administration (FAA) refers to the loss of separation standards between aircraft as an operational error (OE). The extent to which separation is lost determines the severity of the error. The first study examined the relationships between error occurrence, controller workload (number of aircraft and traffic complexity), and causal factors involved. The FAA's Final Operational Error/Deviation Reports for ARTCC facilities during calendar years 1985-88 comprised the data base. A majority of the errors occurred under conditions of below average (25 percent) or average (39 percent) complexity. Complexity and number of aircraft were highly correlated. However, there was a significant difference across facilities in average workload during an event. Improved guidelines for quality assurance personnel are needed to insure a more standardized determination and reporting of workload dimensions. Results suggest that the frequency of some of the causal factors varied in response to changes in number of aircraft worked and traffic complexity. The second study analyzed the workload and causal factors related to the severity of OE's at ARTCC's during 1988-91. Neither the number of aircraft being worked nor air traffic complexity were significantly associated with severity. In general, the causal factors that resulted in greater severity likely involved reduced situation awareness by the controller. The relationship of aircraft profiles and flight levels with OE severity is examined. Facility level differences are reviewed regarding controller workload and awareness of the developing error. More in depth information is needed to determine precisely the manner in which alterations in workload influence the nature of the error process. Both studies point to the need for increasing the level of objectivity in the operational error investigation process. Author (revised)

WORLDWIDE VESSEL LOCATING AND TRACKING SYSTEM, VOLUME 1 Final Report, Oct. 1991 - Dec. 1992
Kevin J. ODonnell and David A. Amos Dec. 1992 135 p Prepared in cooperation with Maritime Administration, Washington, DC Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DTMA91-91-C-10038)
(PB93-193217; MA-RD-840-93000-Vol-1) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report contains an assessment of the possible design and implementation of an automated worldwide Vessel Locating and Tracking System (VESLOTS). During the Technology Assessment task, viable systems were identified for each technology class (i.e., navigation, communication, and display/interface) and each of three geographic operating regions (i.e., worldwide, coastal U.S./Great Lakes, and inland waterway). During the User Requirements analysis task, potential VESLOTS operators and users were surveyed to amass a set of operational requirements for a VESLOTS implementation based on five criteria: message data content, navigation system, communication system, display/interface, and land link. AUTOMATION AND COGNITION IN AIR TRAFFIC CONTROL: AN EMPIRICAL INVESTIGATION Final Report
O. U. Vortac (Oklahoma Univ., Norman.), Mark B. Edwards (Oklahoma Univ., Norman.), Dana K. Fuller (Oklahoma Univ., Norman.), and Carol A. Manning Feb. 1994 20 p
(Contract DTFA02-91-C-91089)
(DOT/FAA/AM-94/3) Avail: CASI HC A03/MF A01

Several investigators have expressed concern that the imminent automation of air traffic control may have negative consequences on cognitive functioning, and ultimately on performance. These possibilities were investigated empirically by comparing normal, conventional air traffic control with an experimental condition designed to resemble an extreme version of automation. Overall, measures of performance were comparable between conditions. Most of the cognitive measures (attentional demands, visual search, recall of flights, and recall of flight data) were not impaired by the automation analog. Instead, two prospective measures (prospective memory, planning) showed improved performance. The prospective memory advantage is particularly surprising given that the automation-analog group was unable to manipulate external memory aids. Possible reasons for the prospective memory advantage include a reduced workload which allows the controller to get the necessary information in other ways, and a change in the nature of the task resulting from the 'automation' of the strip management module. COMPUTATION OF THE LOADS ON THE AH-1/OLS MODEL ROTOR IN FORWARD FLIGHT AND COMPARISON WITH WIND TUNNEL TESTS
M. Schaffar and J. Haertig 2 Oct. 1992 16 p Presented at the 18th European Rotorcraft Forum, Avignon, France, 15-18 Sep. 1992
(ISL-CO-230/92; ETN-94-95127; PB93-204303) Avail: CASI HC A03/MF A01

The vortex lattice method jointly used with a local conformal mapping (to transform the thin blade into a thick one) is described. In order to validate the aerodynamic code, the results are compared with wind tunnel tests for one flight case of the AH-1/OLS model rotor. The study of the wake shows 4 blade/wake interactions for blade 1 during one revolution but only two parallel interactions occur in the rotor plane; the comparison of the computed and measured blade pressures shows an overestimation on the advancing side and an acceptable agreement on the retreating side. BENT-TIP BLADE FOR AIRCRAFT ROTARY-WING Patent [PALE A EXTREMITE COURBE POUR VOILURE TOURNANTE D'AERONEF]
Alain E. Vuillet, inventor (to ONERA), Jean J. Philippe, inventor (to ONERA), and Andre Desopper, inventor (to ONERA) 30 Mar. 1993 29 p In FRENCH
(CA-Patent-1-315-259; Int-Patent-Class-B64C-27/46; CTN-94-60923)
Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A bent-tip blade for a rotary wing aircraft comprises an attachment for fixing to a hub, a standard part having a leading and trailing edge whose profile has a chord of constant or evolutive length C, and a tip which extends the standard part outwardly, the leading edge of which prolongs the leading edge of the standard part directly rearward. The tip is furthermore inclined downward, and this inclination extends along the entire span of the tip and is continuous after the joint with the standard part up to the furthest edge of the tip such that it follows a curve whose extrados is convex and whose intrados is concave. The tip is not folded around a chord on a part of its span, but is curved progressively downward over all its span. Wind tunnel tests have shown that this continuous curvature is favorable in stationary and forward flight. Compared with a rotary wing blade having a rectilinear and rectangular tip, the curved tip of the invention permits a power gain of at least five percent for a given mass of aircraft. CISTI

SUMMARY OF LIFT AND LIFT/CRUISE FAN POWERED LIFT CONCEPT TECHNOLOGY
Woodrow L. Cook Aug. 1993 92 p
(NASA Order A-25364-D)
(NASA-CR-177619; A-93113; NAS 1.26:177619) Avail: CASI HC A05/MF A01

A summary is presented of some of the lift and lift/cruise fan technology including fan performance, fan stall, ground effects, ingestion and thrust loss, design tradeoffs and integration, control effectiveness and several other areas related to vertical short takeoff and landing (V/STOL) aircraft conceptual design. The various subjects addressed, while not necessarily pertinent to specific short takeoff/vertical landing (STOVL) supersonic designs being considered, are of interest to the general field of lift and lift/cruise fan aircraft designs and may be of importance in the future. The various wind tunnel and static tests reviewed are: (1) the Doak VZ-4 ducted fan, (2) the 0.57 scale model of the Bell X-22 ducted fan aircraft, (3) the Avrocar, (4) the General Electric lift/cruise fan, (5) the vertical short takeoff and landing (V/STOL) lift engine configurations related to ingestion and consequent thrust loss, (6) the XV-5 and other fan-in-wing stall consideration, (7) hybrid configurations such as lift fan and lift/cruise fan or engines, and (8) the various conceptual design studies by air-frame contractors. Other design integration problems related to small and large V/STOL transport aircraft are summarized including lessons learned during more recent conceptual design studies related to a small executive V/STOL transport aircraft. Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A landing gear apparatus is comprised of a pivoting casing in which a shock absorber rod is mounted projecting downward with respect to the casing and movable in an axial direction. A swivelling beam is mounted to pivot at a lower end from the shock absorber rod and supports a wheel train fore and aft. The upper branch of a linkage, comprising an upper and lower branch connected to each other in an articulated fashion, is connected to the casing in an articulated manner, and the lower branch is connected in an articulated manner to the swivelling beam. Blockage means are provided for limiting the downward pivoting movement of the upper branch of the linkage while the shock absorber rod is not completely extended. During all phases of pivoting of the swivelling beam, only the lower branch of the linkage pivots, such that the force transmitted by the linkage to the casing is directed following the longitudinal direction of the lower branch of the linkage. The blockage means can be either an abutment on the lower branch of the linkage or a telescoping connecting rod between the upper branch of the linkage and the casing. CISTI

STUDIES OF SHUTTLE ORBITER ARRESTMENT SYSTEM
Pamela A. Davis and Sandy M. Stubbs Dec. 1993 88 p Original contains color illustrations
(RTOP 505-63-10-02)
(NASA-TP-3370; L-17186; NAS 1.60:3370) Avail: CASI HC A05/MF A01; 5 functional color pages

Scale model studies of the Shuttle Orbiter Arrestment System (AS) were completed with a 1/27.5-scale model at the NASA Langley Research Center. The purpose of these studies was to determine the proper configuration for a net arrestment system to bring the orbiter to a safe stop with minimal damage in the event of a runway overrun. Tests were conducted for runway on-centerline and off-centerline engagements at simulated speeds up to approximately 100 knots (full scale). The results of these tests defined the interaction of the net and the orbiter, the dynamics of off-centerline engagements, and the maximum number of vertical net straps that may become entangled with the nose gear. In addition to these tests, a test program with a 1/8-scale model was conducted by the arrestment system contractor, and the results are presented in the appendix. Author (revised)

INTEGRATED AIRFRAME DESIGN TECHNOLOGY [LES TECHNOLOGIES POUR LA CONCEPTION INTEGREE DES CELLULES]
Dec. 1993 173 p In ENGLISH and FRENCH Workshop held in Antalya, Turkey, 19-20 Apr. 1993
(AGARD-R-794; ISBN-92-835-0729-0) Copyright Avail: CASI HC A08/MF A02

Integrated airframe design embraces the concept of bringing together all of the aspects of airframe design, including various disciplines such as structures, materials, aerodynamics, controls, and manufacturing, from conceptual design all the way through manufacturing. It also includes the sub-disciplines which are involved in each discipline and the interactions these have with one another. Moreover, an IAD process also affects the organizational structure of the personnel. In order to provide a broad-based approach to evaluating and identifying future research and development directions required to provide IAD technology, the First Integrated Airframe Design Technology Workshop, sponsored by AGARD, was held in Antalya, Turkey on 19-20 Apr. 1993. This document summarizes the output of that Workshop. For individual titles, see N94-24314 through N94-24327.

Recent advances in computer technology that are likely to impact structural analysis and design of flight vehicles are reviewed. A brief summary is given of the advances in microelectronics, networking technologies, and in the user-interface hardware and software. The major features of new and projected computing systems, including high performance computers, parallel processing machines, and small systems, are described. Advances in programming environments, numerical algorithms, and computational strategies for new computing systems are reviewed. The impact of the advances in computer technology on structural analysis and the design of flight vehicles is described. A scenario for future computing paradigms is presented, and the near-term needs in the computational structures area are outlined. Author (revised)

The successful and timely transition of new product technologies to weapon systems depends heavily on the technical maturity, flexibility, and cost effectiveness of the critical manufacturing processes and systems required to turn these technologies into tangible products. The whole concept of Integrated Product Process Development (a.k.a. Concurrent Engineering) encourages and facilitates the parallel design and development of these manufacturing processes and systems with the design and development of the product. As a result of new computer aided technologies and increased emphasis on manufacturing design, new tools and methodologies are emerging that will facilitate the early consideration of manufacturing in design. This paper will address the development of two such tools: Producibility Methodology; and Tools and Virtual Manufacturing. These tools will enhance the effectiveness of manufacturing engineers who are integrated product process development team members and enable design engineers to better understand the potential downstream implications of early design decisions. Integrated Design Technology has been pushed to a large extent by the tremendous progress achieved in the last two decades in the field of computational techniques with regard to flow simulation, engineering, and manufacturing. This paper concentrates on the impact of CFD on the overall design process reviewed from the view of aircraft industry in Germany. Selected examples will be given for applications of CFD during design and development of major products of European aerospace industry without claiming for completeness. General product categories and technology areas involved will be identified as having large potential for CFD and supercomputing efforts. In addition, present technology thrusts will be discussed, and examples for the impact of CFD and supercomputing demonstrated by applications in various programs will be given. Author (revised)

Technology readiness and the available infrastructure is assessed for timely computational simulation of concurrent engineering for propulsion

systems. Results for initial coupled multidisciplinary, fabrication-process, and system simulators are presented including uncertainties inherent in various facets of engineering processes. An approach is outlined for computationally formalizing the concurrent engineering process from cradle-to-grave via discipline dedicated workstations linked with a common database.

British Aerospace is Britain's largest Manufacturing Group. Its products are divided into the following groups: Defense Systems, Commercial Aircraft, Cars, Civil Engineering, Property Development, Construction, and Project Management. BAe Defense is the largest defense company in Europe with a turnover of 4.2 billion British pounds. Its exports account for over 70 percent of the total sales. The Military Aircraft Division is an important part of the BAe Defense group. Its major projects are centered around the HAWK, HARRIER, TORNADO, and the European Fighter Aircraft EFA projects. The first part of this paper presents some ideas for the investigation and improvement of developmental processes. Typical processes are shown using the Structured Analysis and Design Technique (SADT) and a process flow diagram. In the second part, a redesigned process chain for the design and manufacturing of complex composite parts is explained. Two examples show the functionality of the newly developed constructive design model for this process. Author (revised)

The Integrated Structural Mechanics System (ISSY) is a modular structured tool used to perform a variety of different structural calculations on aircraft structures. ISSY integrates all model generation, analysis and evaluation programs used in structural mechanics under one user interface, and operates a common data base for all these programs. ISSY can be used to generate and analyze calculation models of structural assemblies (fuselage, wings, stabilizers, etc). This is performed by an interactive preprocessor implemented in ISSY. These calculations provide data for both the finite element analysis and for strength analysis, thereby avoiding redundancy of data. Model generation is supported by the use of parameterized standard models (and/or standard sub-models). In addition, model generation is made easier by comprehensive ISSY libraries which provide material data on aluminum, composites, in addition to geometric data on profile sections and rivet allowables. The geometry input data can be directly copied from the component loft data files. The model input data and calculation results are stored in relational data tables which can be analyzed by the postprocessor implemented in ISSY. In addition other modules convert conventionally generated calculation models into ISSY format and generate load case data. To aid partners work on international joint projects, ISSY is compatible with both standard NASTRAN and ISSY processed input and output data. A documentation of model and result data can be obtained in every phase of the justification report. Author

The process of designing aircraft structure requires many functional disciplines and associated interdisciplinary coupling. To achieve optimal performance, the various disciplines must work closely together and effectively exchange large amounts of pertinent data. In the past, this was accomplished either with independent analysis tools that were not tightly coupled or with a single analysis tool that lacked the required fidelity to truly support the needs of more than one discipline. In addition, the analyses were performed in series rather than concurrently. A major impediment to process improvement was the lack of a common geometry database that could be utilized by all disciplines required to support structural design. The rapid growth of computational capability and the gradual acceptance by engineers and management to the use of automated processes and common databases has allowed McDonnell Douglas Aerospace (MDA) to implement a concurrent engineering approach to structural design. Our present aircraft design process combines a common geometry approach and existing analysis tools with the power of engineering workstations to manipulate an integrated design database to arrive at an optimum design solution. Our modular approach divides the design process into smaller, more manageable tasks that can be performed concurrently. It achieves 'buy-in' from each engineering and manufacturing discipline by incorporating existing specialized design tools that have been developed by those groups and introduced into the process without taking away ownership. We use common geometry principles, neutral file structures, widely accepted third party and company proprietary applications coupled with consistent naming conventions and file management to achieve our integrated design methodology solution. The present system optimizes the vehicle structure for minimum weight against a given set of design requirements. It is currently used to evaluate advanced vehicles such as NASP and is also being applied to more conventional aircraft. In the future, capabilities will be added to this analysis system that allow it to be applied to detail design problems as well as increasing the fidelity of advanced design solutions. The major increase in capability will result from adding direct access to the computer aided design geometry and also in the incorporation of standard analysis checks into the system. We will design the architecture of the system such that new engineering and manufacturing applications can be easily added. This paper will discuss the evolution of the MDA integrated design methodology from the 80's to the present as well as our vision of the future. Author

Structural optimization software bears a great promise in multidisciplinary design as an effective way to find an optimal balance between the requirements from different disciplines. Due to the evolution of the airworthiness requirements and the increased complexity of aircraft systems it has become increasingly more difficult in the last few decades to establish the design loads. Thus, a clear need exists for quick and reliable load estimation procedures. The paper discusses some measures that can be taken to improve the load definition process. Finally, some examples of successful application of structural optimization software at Fokker Aircraft are given. The primary advantage of structural optimization software is that it aids a skilled designer in gaining a feel for the design space. It should aid the designer in his creative task instead of distracting his attention to using the software. This requires the software to be user friendly and to have built-in features for global and local sensitivity studies.

INFLUENCE OF ACTIVE CONTROLS ON THE DESIGN PROCESS OF A LARGE TRANSPORT AIRCRAFT

M. Molzow and H. Zimmermann (Deutsche Airbus G.m.b.H., Bremen, Germany.) *In* AGARD, Integrated Airframe Design Technology Dec. 1993 12 p (For primary document see N94-24313 06-05)
Copyright Avail: CASI HC A03/MF A02

The high complexity of an active controlled civil transport aircraft design with its multiple interactions between the different disciplines was presented. It was highlighted that in future design of this kind, different design procedures have to be established with the target to reduce the dominance of one discipline by a multidisciplinary optimization process to ensure an overall aircraft optimum. This has the consequence that the data availability in a certain quality (stiffnesses, aero data, systems data) must be better synchronized with the needs of the user of these data (handling quality, system, loads, flutter, structures) and that cost functions are introduced in the beginning of the design work to ensure a balanced design. It is the firm belief of the authors that already this would be an important step forward. Active Control systems are rather easily capable of being integrated by having in mind to use signals from additional sensors distributed over the A/C than are available from the ADIRU. There are some doubts that all these relations and interactions in real aircraft design can be replaced one day by a totally automated process but certainly more parts have to be put into a process chain to improve quality and safe design time. Current aircraft industry design practices produce high quality, safe, and affordable aircraft. However, future advanced and integrated methods offer the opportunity to significantly reduce the cost and development time of aircraft designs. This paper presents an overview of the current design process and an example for subsonic transport wing box design. It also describes a future process which is presently being implemented at the Douglas Aircraft Company, i.e. the Aeroelastic Design Optimization Program (ADOP), and its application to a similar subsonic transport wing. Specifically, stress and flutter are optimized and compression surface buckling and tension surface damage tolerance are integrated. Finally, the future direction of ADOP will be outlined which includes integration of aeroelastic loads, durability and damage tolerance, and concurrent structure and active controls optimization. In aeronautics, the age of high creativity, like the one in the fifties with the introduction of jet engines or the one in the thirties which started the age of monoplanes with metallic shell structures, is passed. Today, we are in a situation in which the final increment in basic performance (maximum speed, maneuver capability) is usually excessively expensive. It is now necessary to look to marginal areas to gain improvements in performance, to use new materials such as carbon fibers to tailor the structure to specific needs, and to simplify, with the help of electronics and servomechanisms, complicated mechanical systems to obtain aircraft architectures otherwise impossible to fly. But this is not enough; it is absolutely necessary to also improve the cost effectiveness by increasing the reliability, availability, and supportability of the weapon system, thereby reducing the usage cost and the production cost of the aircraft. This is not any more achievable using the single man capabilities on a single discipline, but it requires a new type of working organization which uses sophisticated means of calculation, integrated in order to optimize the overall design, and which compresses the time of the process by exploiting the synergism of the interdisciplinary couplings, overlapping as much as possible the design and manufacturing phases. Alenia Defense Aircraft Division, being involved in several programs, both by itself and in international cooperation, has followed this evolution and is actively pursuing the adequacy of its operative structure to the new requirements by adopting advanced technology processes. Effective computational simulation procedures are described for modeling the inherent multi-disciplinary interactions for determining the true response of propulsion systems. Results are presented for propulsion system responses including multi-discipline coupling effects via (1) coupled multi-discipline tailoring, (2) an integrated system of multidisciplinary simulators, (3) coupled material-behavior/fabrication-process tailoring, (4) sensitivities using a probabilistic simulator, and (5) coupled materials/structures/fracture/probabilistic behavior simulator. The results show that the best designs can be determined if the analysis/tailoring methods account for the multi-disciplinary coupling effects. The coupling across disciplines can be used to develop an integrated interactive multi-discipline numerical propulsion system simulator. Author

First, it is reminded that organization of airframe design is directly linked to the performances of available tools. As a matter of fact, they condition the number and nature of project iterations. The organization which should nowadays be recommended in view of the means of CAD, computation and mathematical optimization at our disposal is presented and analyzed. This leads to a first design, followed by experimental verifications with a key role for flight tests. The final design is checked with the help of calculations models calibrated on tests. Then the new tools which are the factors of future evolution of design methodology are examined: to dispose of 'Design History' corresponding to the whole data of the process; parametric CAD and shape optimization; multidisciplinary optimization; 'Feature' Design; improvement of computation methods. As a conclusion we insist on the fact that aircraft manufacturers, CAD suppliers, and scientific searchers will be well advised to create a dialogue as to future design methodology. Author (revised)

AIRCRAFT EMPENNAGE STRUCTURAL DETAIL DESIGN
Greg Meholic, Rhonda Brown, Melissa Hall, Robert Harvey, Michael Singer, and Gustavo Tella 19 Apr. 1993 73 p
(Contract NASw-4435)
(NASA-CR-195496; NAS 1.26:195496) Avail: CASI HC A04/MF A01

This project involved the detailed design of the aft fuselage and empennage structure, vertical stabilizer, rudder, horizontal stabilizer, and elevator for the Triton primary flight trainer. The main design goals under consideration were to illustrate the integration of the control systems devices used in the tail surfaces and their necessary structural supports as well as the elevator trim, navigational lighting system, electrical systems, tail-located ground tie, and fuselage/cabin interface structure. Accommodations for maintenance, lubrication, adjustment, and repairability were devised. Weight, fabrication, and (sub)assembly goals were addressed. All designs were in accordance with the FAR Part 23 stipulations for a normal category aircraft. Author

In the fall of 1992, the TAC Team was presented with a Request for Proposal (PFP) for a mid-size (250-350 passenger) commercial transport. The aircraft was to be extremely competitive in the areas of passenger comfort, performance, and economic aspects. Through the use of supercritical airfoils, a technologically advanced Very High By-pass Ratio (VHBR) turbofan engine, a low overall drag configuration, a comparable interior layout, and mild use of composites, the JB-300 offers an economically viable choice to the airlines. The cents per passenger mile of the JB-300 is 1.76, which is considerably lower than current aircraft in the same range. Overall, the JB-300 is a technologically advanced aircraft, which will meet the demands of the 21st century. Author (revised)

DESIGN OF A VEHICLE BASED SYSTEM TO PREVENT OZONE LOSS

Sean R. Lynn, Deborah Bunker, Thomas D. Hesbach, Jr., Everett B. Howerton, G. Hreinsson, E. Kirk Mistr, Matthew E. Palmer, Claiborne Rogers, Dayna S. Tischler, and Daniel J. Wrona et al 28 Jul. 1993 70 p
(Contract NASw-4435)
(NASA-CR-195498; NAS 1.26:195498) Avail: CASI HC A04/MF A01

Reduced quantities of ozone in the atmosphere allow greater levels of ultraviolet light (UV) radiation to reach the earth's surface. This is known to cause skin cancer and mutations. Chlorine liberated from Chlorofluorocarbons (CFC's) and natural sources initiate the destruction of stratospheric ozone through a free radical chain reaction. The project goals are to understand the processes which contribute to stratospheric ozone loss, examine ways to prevent ozone loss, and design a vehicle-based system to carry out the prevention scheme. The 1992/1993 design objectives were to accomplish the first two goals and define the requirements for an implementation vehicle to be designed in detail starting next year. Many different ozone intervention schemes have been proposed though few have been researched and none have been tested. A scheme proposed by R.J. Cicerone, Scott Elliot and R.P.Turco late in 1991 was selected because of its research support and economic feasibility. This scheme uses hydrocarbon injected into the Antarctic ozone hole to form stable compounds with free chlorine, thus reducing ozone depletion. Because most polar ozone depletion takes place during a 3-4 week period each year, the hydrocarbon must be injected during this time window. A study of the hydrocarbon injection requirements determined that 100 aircraft traveling Mach 2.4 at a maximum altitude of 66,000 ft. would provide the most economic approach to preventing ozone loss. Each aircraft would require an 8,000 nm. range and be able to carry 35,000 lbs. of propane. The propane would be stored in a three-tank high pressure system. Missions would be based from airport regions located in South America and Australia. To best provide the requirements of mission analysis, an aircraft with L/D(sub cruise) = 10.5, SFC = 0.65 (the faculty advisor suggested that this number is too low) and a 250,000 lb TOGW was selected as a baseline. Modularity and multi-role functionality were selected to be key design features. Modularity provides ease of turnaround for the down-time critical mission. Multi-role functionality allows the aircraft to be used beyond its design mission, perhaps as an High Speed Civil Transport (HSCT) or for high altitude research. Author (revised)

AIRCRAFT WING STRUCTURE DETAIL DESIGN

Garrett L. Sager, Ron Roberts, Bob Mallon, Mohamed Alameri, and Bill Steinbach 14 Apr. 1993 36 p
(Contract NASw-4435)
(NASA-CR-195485; NAS 1.26:195485) Avail: CASI HC A03/MF A01

The provisions of this project call for the design of the structure of the wing and carry-through structure for the Viper primary trainer, which is to be certified as a utility category trainer under FAR part 23. The specific items to be designed in this statement of work were Front Spar, Rear Spar, Aileron Structure, Wing Skin, and Fuselage Carry-through Structure. In the design of these parts, provisions for the fuel system, electrical system, and control routing were required. Also, the total weight of the entire wing planform could not exceed 216 lbs. Since this aircraft is to be used as a primary trainer, and the SOW requires a useful life of 107 cycles, it was decided that all of the principle stresses in the structural members would be kept below 10 ksi. The only drawback to this approach is a weight penalty. Derived from text

(NASA-CR-195510; NAS 1.26:195510) Avail: CASI HC A07/MF A02

A recent white paper entitled 'From the Sea' has spotlighted the need for Naval Aviation to provide overland support to joint operations. The base for this support, the Aircraft Carrier (CVN), will frequently be unable to operate within close range of the battleground because of littoral land-based air and subsurface threats. A high speed, long range, carrier capable aircraft would allow the CVN to provide timely support to distant battleground operations. Such an aircraft, operating as a Deck-Launched Interceptor (DLI), would also be an excellent counter to Next Generation Russian Naval Aviation (NGRNA) threats consisting of supersonic bombers, such as the Backfire, equipped with the next generation of high-speed, long-range missiles. Additionally, it would serve as an excellent high speed Reconnaissance airplane, capable of providing Battle Force commanders with timely, accurate pre-mission targeting information and post-mission Bomb Damage Assessment (BDA). Recent advances in computational hypersonic airflow modeling has produced a method of defining aircraft shapes that fit a conical shock flow model to maximize the efficiency of the vehicle. This 'Waverider' concept provides one means of achieving long ranges at high speeds. A Request for Proposal (RFP) was issued by Professor Conrad Newberry that contained design requirements for an aircraft to accomplish the above stated missions, utilizing Waverider technology. NASA ADVANCED DESIGN PROGRAM. DESIGN AND ANALYSIS OF A RADIO-CONTROLLED FLYING WING AIRCRAFT

3 May 1993 100 p
(Contract NASw-4435)
(NASA-CR-195515; NAS 1.26:195515) Avail: CASI HC A05/MF A02

The main challenge of this project was to design an aircraft that will achieve stability while flying without a horizontal tail. The project focused on both the design, analysis and construction of a remotely piloted, elliptical shaped flying wing. The design team was composed of four sub-groups each of which dealt with the different aspects of the design, namely aerodynamics, stability and control, propulsion, and structures. Each member of the team initially researched the background information pertaining to specific facets of the project. Since previous work on this topic was limited, most of the focus of the project was directed towards developing an understanding of the natural instability of the aircraft. Once the design team entered the conceptual stage of the project, a series of compromises had to be made to satisfy the unique requirements of each sub-group. As a result of the numerous calculations and iterations necessary, computers were utilized extensively. In order to visualize the design and layout of the wing, engines and control surfaces, a solid modeling package was used to evaluate optimum design placements. When the design was finalized, construction began with the help of all the members of the project team. The nature of the carbon composite construction process demanded long hours of manual labor. The assembly of the engine systems also required precision hand work. The final product of this project is the Elang, a one-of-a-kind remotely piloted aircraft of composite construction powered by two ducted fan engines. Author (revised)

A PARAMETRIC STUDY OF HARMONIC ROTOR HUB LOADS
Chengjian He Nov. 1993 60 p
(Contract NAS1-19000; RTOP 505-63-36)
(NASA-CR-4558; NAS 1.26:4558) Avail: CASI HC A04/MF A01

A parametric study of vibratory rotor hub loads in a nonrotating system is presented. The study is based on a CAMRAD/JA model constructed for the GBH (Growth Version of Blackhawk Helicopter) Mach-scaled wind tunnel rotor model with high blade twist (-16 deg). The theoretical hub load predictions are validated by correlation with available measured data. Effects of various blade aeroelastic design changes on the harmonic nonrotating frame hub loads at both low and high forward flight speeds are investigated. The study aims to illustrate some of the physical mechanisms for change in the harmonic rotor hub loads due to blade design variations. Author (revised)

With the collapse of the former Soviet Union and the emergence of the United Nations actively pursuing a peace keeping role in world affairs, the United States has been forced into a position as the world's leading peace enforcer. It is still a very dangerous world with seemingly never ending ideological, territorial, and economic disputes requiring the U.S. to maintain a credible deterrent posture in this uncertain environment. This has created an urgent need to rapidly transport large numbers of troops and equipment from the continental United States (CONUS) to any potential world trouble spot by means of a global range/mobility transport aircraft. The most recent examples being Operation Desert Shield/Storm and Operation Restore Hope. To meet this challenge head-on, a request for proposal (RFP) was developed and incorporated into the 1992/1993 AIAA/McDonnell Douglas Corporation Graduate Team Aircraft Design Competition. The RFP calls for the conceptual design and justification of a large aircraft capable of power projecting a significant military force without surface transportation reliance. Derived from text

WIND TUNNEL TEST OF A VARIABLE-DIAMETER TILTROTOR (VDTR) MODEL
David Matuska, Allen Dale, and Peter Lorber Jan. 1994 230 p
(Contract NAS2-13484)
(NASA-CR-177629; A-94018; NAS 1.26:177629) Avail: CASI HC A11/MF A03

This report documents the results from a wind tunnel test of a 1/6th scale Variable Diameter Tiltrotor (VDTR). This test was a joint effort of NASA Ames and Sikorsky Aircraft. The objective was to evaluate the aeroelastic and performance characteristics of the VDTR in conversion, hover, and cruise. The rotor diameter and nacelle angle of the model were remotely changed to represent tiltrotor operating conditions. Data is presented showing the propulsive force required in conversion, blade loads, angle of attack stability and simulated gust response, and hover and cruise performance. This test represents the first wind tunnel test of a variable diameter rotor applied to a tiltrotor concept. The results confirm some of the potential advantages of the VDTR and establish the variable diameter rotor a viable candidate for an advanced tiltrotor. This wind tunnel test successfully demonstrated the feasibility of the Variable Diameter rotor for tilt rotor aircraft. A wide range of test points were taken in hover, conversion, and cruise modes. The concept was shown to have a number of advantages over conventional tiltrotors such as reduced hover downwash with lower disk loading and significantly reduced longitudinal gust response in cruise. In the conversion regime, a high propulsive force was demonstrated for sustained flight with acceptable blade loads. The VDTR demonstrated excellent gust response capabilities. The horizontal gust response correlated well with predictions revealing only half the response to turbulence of the conventional civil tiltrotor. Author (revised)

VLCT-13: A COMMERCIAL TRANSPORT FOR THE 21ST CENTURY
Pamela Beal, Terri Sowels, Hitoshi Takahashi, Matt Cotton, Will Balanon, and Manuel Parayo 14 May 1993 72 p
(Contract NASw-4435)
(NASA-CR-195492; NAS 1.26:195492) Avail: CASI HC A04/MF A01

The growth of the Pacific Rim market has spurred airframers to begin feasibility studies of a large commercial transport. By the year 2001, 30 million travelers are expected to travel the Transpacific. A transport capable of hauling 800 PAX and 30,000 pounds of cargo, 7,000 nm is of specific interest. Special problems associated with this design are configuration, landing gear, passenger safety, airport compatibility, and engine thrust. A group of students at the California Polytechnic State University at San Luis Obispo developed a very large commercial transport, VLCT-13, conventional looking design which is both comfortable and economical. Passenger comfort includes seat pitches of 34 in and 40 in, width's of 23 in and 25 in, respectfully, and a 27 ft diameter cross section. A direct operating cost of 2.3 cents per passenger per seat-mile is estimated for this airplane design. The airplane market price is estimated to be $195 million 1993 dollars based on an aircraft take off weight of 1.4 million pounds. The problems associated with the VLCT-13 are discussed and possible solutions are presented. Author (revised)

THE BLUE EMU Final Design Proposal
Doug Descalzi, John Gillett, Carlton Gordon, Ed Keener, Ken Novak, and Laura Puente Apr. 1993 125 p
(Contract NASw-4435)
(NASA-CR-195535; NAS 1.26:195535) Avail: CASI HC A06/MF A02

The primary goal in designing the Blue Emu was to provide an airline with a cost efficient and profitable means of transporting passengers between the major cities in Aeroworld. The design attacks the market where a demand for inexpensive transportation exists and for this reason the Blue Emu is an attractive investment for any airline. In order to provide a profitable aircraft, special attention was paid to cost and economics. For example, in manufacturing, simplicity was stressed in structural design to reduce construction time and cost. Aerodynamic design employed a tapered wing which reduced the induced drag coefficient while also reducing the weight of the wing. Even the propulsion system was selected with cost effectiveness in mind, yet also to maintain the marketability of the aircraft. Thus, in every aspect of the design, consideration was given to economics and marketability of the final product. Author (revised)

THE AIRPLANE: A SIMULATED COMMERCIAL AIR TRANSPORTATION STUDY Final Design Proposal
Mark DAuteuil, Pete Geniesse, Michael Hunniford, Kathleen Lawler, Elena Quirk, and Michael Tognarelli Apr. 1993 176 p
(Contract NASw-4435)
(NASA-CR-195525; NAS 1.26:195525) Avail: CASI HC A09/MF A02

The 'Airplane' is a moderate-range, 70 passenger aircraft. It is designed to serve demands for flights up to 10,000 feet and it cruises at 32 ft/s. The major drivers for the design of the Airplane are economic competitiveness, takeoff performance, and weight minimization. The Airplane is propelled by a single Astro 15 electric motor and a Zinger 12-8 propeller. The wing section is a Spica airfoil which, because of its flat bottom, provides simplicity in manufacturing and thus helps to cut costs. The wing is constructed of a single load bearing mainspar and shape-holding ribs coated with Monokote skin, lending to a light weight structural makeup. The fuselage houses the motor, flight deck and passenger compartments as well as the fuel and control actuating systems. The wing will be attached to the top of the fuselage as will the fuel and control actuator systems for easy disassembly and maintenance. The aircraft is maneuvered about its pitch axis by means of an aft elevator on the flat plate horizontal tail. The twin vertical tail surfaces are also flat plates and each features a rudder for both directional and roll control. Along with wing dihedral, the rudders will be used to roll the aircraft. The Airplane is less costly to operate at its own maximum range and capacity as well as at its maximum range and the HB-40's maximum capacity than the HB-40. Derived from text

(NASA-CR-195500; NAS 1.26:195500) Avail: CASI HC A06/MF A02

The world is rapidly changing from one with two military superpowers, with which most countries were aligned, to one with many smaller military powers. In this environment, the United States cannot depend on the availability of operating bases from which to respond to crises requiring military intervention. Several studies (e.g. the SAB Global Reach, Global Power Study) have indicated an increased need to be able to rapidly transport large numbers of troops and equipment from the continental United States to potential trouble spots throughout the world. To this end, a request for proposals (RFP) for the concept design of a large aircraft capable of 'projecting' a significant military force without reliance on surface transportation was developed. These design requirements are: minimum payload of 400,000 pounds at 2.5 g maneuver load factor; minimum unfueled range of 6,000 nautical miles; and aircraft must operate from existing domestic air bases and use existing airbases or sites of opportunity at the destination. AEROELASTIC RESPONSE AND STABILITY OF TILTROTORS WITH ELASTICALLY-COUPLED COMPOSITE ROTOR BLADES Ph.D. Thesis
Mark W. Nixon 1993 448 p
(NASA-TM-108758; NAS 1.15:108758) Avail: CASI HC A19/MF A04

There is a potential for improving the performance and aeroelastic stability of tiltrotors through the use of elastically-coupled composite rotor blades. To study the characteristics of tiltrotors with these types of rotor blades it is necessary to formulate a new analysis which has the capabilities of modeling both a tiltrotor configuration and an anisotropic rotor blade. Background for these formulations is established in two preliminary investigations. In the first, the influence of several system design parameters on tiltrotor aeroelastic stability is examined for the high-speed axial flight mode using a newly-developed rigid-blade analysis with an elastic wing finite element model. The second preliminary investigation addresses the accuracy of using a one-dimensional beam analysis to predict frequencies of elastically-coupled highly-twisted rotor blades. Important aspects of the new aeroelastic formulations are the inclusion of a large steady pylon angle which controls tilt of the rotor system with respect to the airflow, the inclusion of elastic pitch-lag coupling terms related to rotor precone, the inclusion of hub-related degrees of freedom which enable modeling of a gimballed rotor system and engine drive-train dynamics, and additional elastic coupling terms which enable modeling of the anisotropic features for both the rotor blades and the tiltrotor wing. Accuracy of the new tiltrotor analysis is demonstrated by a comparison of the results produced for a baseline case with analytical and experimental results reported in the open literature. Two investigations of elastically tailored blades on a baseline tiltrotor are then conducted. One investigation shows that elastic bending-twist coupling of the rotor blade is a very effective means for increasing the flutter velocity of a tiltrotor, and the magnitude of coupling required does not have an adverse effect on performance or blade loads. The second investigation shows that passive blade twist control via elastic extension-twist coupling of the rotor blade has the capability of significantly improving tiltrotor aerodynamic performance. This concept, however, is shown to have, in general, a negative impact on stability characteristics. Author

THE AC-120: THE ADVANCED COMMERCIAL TRANSPORT
David Duran, Ernest Griffin, Saul Mendoza, Son Nguyen, Tim Pickett, and Clemm Noernberg 14 May 1993 89 p Original contains color illustrations
(Contract NASw-4435)
(NASA-CR-195491; NAS 1.26:195491) Avail: CASI HC A05/MF A01: 3 functional color pages

The main objective of this design was to fulfill a need for a new airplane to replace the aging 100 to 150 passenger, 1500 nautical mile range aircraft such as the Douglas DC9 and Boeing 737-100 airplanes. After researching the future aircraft market, conducting extensive trade studies, and analysis on different configurations, the AC-120 Advanced Commercial Transport final design was achieved. The AC-120's main design features include the incorporation of a three lifting surface configuration which is powered by two turboprop engines. The AC-120 is an economically sensitive aircraft which meets the new FM Stage Three noise requirements, and has lower NO(x) emissions than current turbofan powered airplanes. The AC-120 also improves on its contemporaries in passenger comfort, manufacturing, and operating cost. Author (revised)

INTEGRATED DESIGN AND MANUFACTURING FOR THE HIGH SPEED CIVIL TRANSPORT Final Report
Jun. 1993 201 p
(Contract NASw-4435)
(NASA-CR-195511; NAS 1.26:195511) Avail: CASI HC A10/MF A03

In June 1992, Georgia Tech's School of Aerospace Engineering was awarded a NASA University Space Research Association (USRA) Advanced Design Program (ADP) to address 'Integrated Design and Manufacturing for the High Speed Civil Transport (HSCT)' in its graduate aerospace systems design courses. This report summarizes the results of the five courses incorporated into the Georgia Tech's USRA ADP program. It covers

AE8113: Introduction to Concurrent Engineering, AE4360: Introduction to CAE/CAD, AE4353: Design for Life Cycle Cost, AE6351: Aerospace Systems Design One, and AE6352: Aerospace Systems Design Two. AE8113: Introduction to Concurrent Engineering was an introductory course addressing the basic principles of concurrent engineering (CE) or integrated product development (IPD). The design of a total system was not the objective of this course. The goal was to understand and define the 'up-front' customer requirements, their decomposition, and determine the value objectives for a complex product, such as the high speed civil transport (HSCT). A generic CE methodology developed at Georgia Tech was used for this purpose. AE4353: Design for Life Cycle Cost addressed the basic economic issues for an HSCT using a robust design technique, Taguchi's parameter design optimization method (PDOM). An HSCT economic sensitivity assessment was conducted using a Taguchi PDOM approach to address the robustness of the basic HSCT design. AE4360: Introduction to CAE/CAD permitted students to develop and utilize CAE/CAD/CAM knowledge and skills using CATIA and CADAM as the basic geometric tools. AE6351: Aerospace Systems Design One focused on the conceptual design refinement of a baseline HSCT configuration as defined by Boeing, Douglas, and NASA in their system studies. It required the use of NASA's synthesis codes FLOPS and ACSYNT. A criterion called the productivity index (P.I.) was used to evaluate disciplinary sensitivities and provide refinements of the baseline HSCT configuration. AE6352: Aerospace Systems Design Two was a continuation of Aerospace Systems Design One in which wing concepts were researched and analyzed in more detail. FLOPS and ACSYNT were again used at the system level while other off-the-shelf computer codes were used for more detailed wing disciplinary analysis and optimization. The culmination of all efforts and submission of this report conclude the first year's efforts of Georgia Tech's NASA USRA ADP. It will hopefully provide the foundation for next year's efforts concerning continuous improvement of integrated design and manufacturing for the HSCT.

AIRCRAFT EMPENNAGE STRUCTURAL DETAIL DESIGN
David Lesnewski, Russ M. Snow, Lisa M. Combs, David Paufler, George Schnieder, and Roxanne Athousake 15 Apr. 1993 56 p
(Contract NASw-4435)
(NASA-CR-195486; NAS 1.26:195486) Avail: CASI HC A04/MF A01

The purpose of this project is to provide an empennage structural assembly that will withstand the operational loads defined in FAR Part 23, as well as those specified in the statement of work, i.e. snow, rain, humidity, tiedown forces, etc. The goal is to provide a simple yet durable lightweight structure that will transfer the aerodynamic forces produced by the tail surfaces through the most efficient load path to the airframe. The structure should be simple and cost-effective to manufacture and repair. All structures meet or exceed loading and fatigue criteria. The structure provides for necessary stiffness and ease of maintenance. Author (revised)

Today's carrier based deck launched intercept (DLI) mission is a vital one that is aimed at protecting the carrier battle group and detering potential adversaries. The assets deployed on our carrier decks are able to complete this mission but with very limited range. The waverider concept has great potential to increase the range of this carrier based mission. As a result, a request for proposals (RFP) was developed which contains design requirements for an aircraft that can complete this mission through the utilization of waverider technology. A GLOBAL RANGE MILITARY TRANSPORT: THE OSTRICH
John Aguiar, Cecilia Booker, Eric Hoffman, James Kramar, Orlando Manahan, Ray Serranzana, and Mike Taylor 14 May 1993 103 p
(Contract NASw-4435)
(NASA-CR-195494; NAS 1.26:195494) Avail: CASI HC A06/MF A02

Studies have shown that there is an increasing need for a global range transport capable of carrying large numbers of troops and equipment to potential trouble spots throughout the world. The Ostrich is a solution to this problem. The Ostrich is capable of carrying 800,000 pounds 6,500 n.m. and returning with 15 percent payload, without refueling. With a technology availability date in 2010 and an initial operating capability of 2015, the aircraft incorporates many advanced technologies including laminar flow control, composite primary structures, and a unique multibody design. By utilizing current technology, such as using McDonnell Douglas C-17 fuselage for the outer fuselages on the Ostrich, the cost for the aircraft was reduced. The cost of the Ostrich per aircraft is $1.2 billion with a direct operating cost of $56,000 per flight hour. The Ostrich will provide a valuable service as a logistical transport capable of rapidly projecting a significant military force or humanitarian aid anywhere in the world.

AIRCRAFT WING STRUCTURAL DETAIL DESIGN (WING, AILERON, FLAPS, AND SUBSYSTEMS)
Robert Downs, Mike Zable, James Hughes, Terry Heiser, and Kenneth Adrian 14 Apr. 1993 40 p
(Contract NASw-4435)
(NASA-CR-195487; NAS 1.26:195487) Avail: CASI HC A03/MF A01

The goal of this project was to design, in detail, the wing, flaps, and ailerons for a primary flight trainer. Integrated in this design are provisions for the fuel system, the electrical system, and the fuselage/cabin carry-through interface structure. This conceptual design displays the general arrangement of all major components in the wing structure, taking into consideration the requirements set forth by the appropriate sections of Federal Aviation Regulation Part 23 (FAR23) as well as those established in the statement of work. WEASEL WORKS SA-150: DESIGN STUDY OF A 100 TO 150 PASSENGER TRANSPORT AIRCRAFT
Kevin Alkema, Michael Comeaux, Timothy Gilbert, Victor Para, and George Toepfer 14 May 1993 110 p
(Contract NASw-4435)
(NASA-CR-195489; NAS 1.26:195489) Avail: CASI HC A06/MF A02

As the year 2000 rapidly approaches, the airlines are faced with an extremely competitive and environmentally restrictive marketplace. In order to survive, commercial air carriers will need to find new ways to lower their direct operating costs, increase load factors and comply with tightening federal and international constraints. The SA-150 has been designed to meet these demands by focusing on the areas of aerodynamic efficiency, an improved level of passenger comfort, and a limited application of advanced technology. The SA-150 has been optimized for a 500 nmi. mission to help the airlines meet the challenges of the short haul, quick turnaround flight. With a maximum capacity of 124 passengers, and full baggage, the SA-150 is also capable of covering a range of 1500 nmi. This additional range capability will provide the airlines with flexibility when scheduling their routes. The aircraft features a 'V' tail, fly-by-wire system and is powered by two turbofans mounted under a twelve aspect ratio wing. The SA-150 will have an initial production run of 800 units and have a purchase price of $37.7 million in 1993 dollars. Author

THE BUNNY: A SIMULATED COMMERCIAL AIR TRANSPORTATION STUDY Final Design Proposal
David Fulton, Patrick Gallagher, William Grannan, Jennifer Martin, Nicole Mastej, and Brett Wujek Apr. 1993 123 p
(Contract NASw-4435)
(NASA-CR-195537; NAS 1.26:195537) Avail: CASI HC A06/MF A02

The Bunny is a single-engine, 100 passenger commercial transport designed to serve the high density short-to-medium range markets in AEROWORLD. The aircraft's design range is 10,000 feet at a cruise velocity of 30 ft/s. The aircraft features a low wing which incorporates polyhedral for roll control. Yaw and pitch control are accomplished by a rudder and elevator, respectively. Propulsion is provided by a nose-mounted Astro 15 electric motor powered by thirteen 1.2 V, 1000 mah batteries with a Zinger 12-6 propeller. The aircraft is structurally designed with a safety factor of

1.5 and is constructed primarily of balsa, bass, and birch wood. Passenger seating is arranged on two levels, with three-abreast on the lower level and two-abreast on the upper level. The factors which had the most significant influence on the final design were the direct operating cost and the take-off distance. The primary strength of The Bunny is its ability to compete economically with the HB-40. At full capacity and mid-range fuel costs, the cost per seat per thousand feet (CPSK) of this aircraft is 25% less than the HB-40. Another principal strength is its ability to operate in all airports in AEROWORLD. Also, The Bunny's two-piece removable wing is an advantage from a transportability standpoint. Derived from text

THE GOLD RUSH: A SIMULATED COMMERCIAL AIR TRANSPORTATION STUDY

Amanda Clarke, Chris Degiorgio, Edmund Galka, Albert Stumm, Lisa Valenta, and Tom Winter Apr. 1993 121 p
(Contract NASw-4435)
(NASA-CR-195528; NAS 1.26:195528) Avail: CASI HC A06/MF A02

The remotely piloted vehicle (RPV) GoldRush was designed to complete the mission of transporting passengers in AeroWorld at a lower cost per seat per thousand feet (CPSPK) than the competition, the HB-40. There were two major factors which were constant considerations in the design process. The cost of manufacturing was the most important. In light of this, the designs were kept as simple as possible while considering trade-offs in performance. For example, the wing was not tapered so that several ribs could be cut at one time. Also of major importance was the takeoff distance. In order to serve all the cities in AeroWorld it was necessary to maintain a takeoff distance requirement of 24 feet. The takeoff distance proved to be the number one force in driving the design process. The Astro 25 engine and 13 inch propellor, a large wing area, and the high lift Wortmann airfoil were all chosen in order to satisfy this objective. Derived from text

THE TRITON: DESIGN CONCEPTS AND METHODS

Greg Meholic, Michael Singer, Percy vanRyn, Rhonda Brown, Gustavo Tella, and Bob Harvey 7 Dec. 1992 48 p
(Contract NASw-4435)
(NASA-CR-195542; NAS 1.26:195542) Avail: CASI HC A03/MF A01

During the design of the C & P Aerospace Triton, a few problems were encountered that necessitated changes in the configuration. After the initial concept phase, the aspect ratio was increased from 7 to 7.6 to produce a greater lift to drag ratio (L/D = 13) which satisfied the horsepower requirements (118 hp using the Lycoming O-235 engine). The initial concept had a wing planform area of 134 sq. ft. Detailed wing sizing analysis enlarged the planform area to 150 sq. ft., without changing its layout or location. The most significant changes, however, were made just prior to inboard profile design. The fuselage external diameter was reduced from 54 to 50 inches to reduce drag to meet the desired cruise speed of 120 knots. Also, the nose was extended 6 inches to accommodate landing gear placement. Without the extension, the nosewheel received an unacceptable percentage (25 percent) of the landing weight. The final change in the configuration was made in accordance with the stability and control analysis. In order to reduce the static margin from 20 to 13 percent, the horizontal tail area was reduced from 32.02 to 25.0 sq. ft. The Triton meets all the specifications set forth in the design criteria. If time permitted another iteration of the calculations, two significant changes would be made. The vertical stabilizer area would be reduced to decrease the aircraft lateral stability slope since the current value was too high in relation to the directional stability slope. Also, the aileron size would be decreased to reduce the roll rate below the current 106 deg/second. Doing so would allow greater flap area (increasing CL(sub max)) and thus reduce the overall wing area. C & P would also recalculate the horsepower and drag values to further validate the 120 knot cruising speed. Author (revised)

THE RTL-46: A SIMULATED COMMERCIAL AIR TRANSPORTATION STUDY Final Report

Christian Dunbar, John Prette, Gerald Andersen, Martin Sprunck, Christine Vogel, and Francisco Rivera Apr. 1993 128 p
(Contract NASw-4435)
(NASA-CR-195524; NAS 1.26:195524) Avail: CASI HC A07/MF A02

The RTL-46 provides an aircraft which utilizes advanced technology within the fictional Aeroworld market to better service the air travel customers and airlines of Aeroworld. The RTL-46 is designed to serve the portion of the travel market which flies less than 10,000 feet per flight. The design cruise velocity for the aircraft is 35 ft/sec, which rapidly expedites travel through Aeroworld. The major focus of the endeavor was to design an aircraft which would serve the Aeroworld market better than the existing aircraft, the HB-40. This could have been done through targeting another portion of the Aeroworld market or through serving the current HB-40 market more effectively. Due to the fact that approximately 70 percent of the potential Aeroworld passengers desired flights of 10,000 ft or less, this range became the target market for the RTL-46. Derived from text

B-2 BOMBER: ASSESSMENT OF DOD'S RESPONSE TO MANDATED CERTIFICATIONS AND REPORTS

3 Nov. 1993 6 p
(AD-A273179; GAO/NSIAD-94-75) Avail: CASI HC A02/MF A01

Department of Defense Authorization Acts for fiscal years 1990, 1992, and 1993 required the Secretary of Defense to deliver to the Congress, certain certifications and reports concerning the B-2 bomber program. The Congress restricted the Air Force's use of about $2.3 billion appropriated in fiscal years 1992 and 1993 for procurement of B-2 Aircraft until those certifications and reports are delivered and an act of the Congress is passed authorizing release of the funds. The authorization acts also call for our office to report to the Congress concerning the certifications and reports submitted by the Secretary. This is an interim report in response to that legislation. A detailed classified report will be issued shortly. DTIC

AIRCRAFT MANEUVERS FOR THE EVALUATION OF FLYING QUALITIES AND AGILITY. VOLUME 2: MANEUVER DESCRIPTIONS AND SECTION GUIDE Final Report, Sep. 1990 - Jun. 1993
David J. Wilson, David R. Riley, and Kevin D. Citurs Aug. 1993 92 p
(Contract F33615-90-C-3600)
(AD-A273685; WL-TR-93-3082-Vol-2) Avail: CASI HC A05/MF A01

A set of aircraft maneuvers was developed to augment evaluation maneuvers used currently by the flying qualities and flight test communities. These maneuvers extend evaluation to full aircraft dynamics throughout the aircraft flight envelope. As a result, a tie was established between operational use and design parameters without losing control of the aircraft evaluation process. Twenty maneuvers are described as an initial set to examine primarily high-angle-of-attack conditions. Perhaps as important as the maneuvers themselves is the method used to select them. These maneuvers will allow direct measurement of flying qualities throughout the flight envelope instead of merely comparing parameters to specification values. DTIC

ADVANCED AVIONICS ARCHITECTURE AND TECHNOLOGY REVIEW. EXECUTIVE SUMMARY AND VOLUME 1: AVIONICS TECH NOLOGY. VOLUME 2: AVIONICS SYSTEMS ENGINEERING Final Report, Jul. 1992 - Aug. 1993
6 Aug. 1993 244 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273630) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this study was to review the current technology base, developing technologies, and the potential to apply them to meet military avionics requirements. The review also examined the technology integration methods used in the avionics community in order to develop a more efficient and more affordable avionics architectural strategy for the future. It provides a bold vision for the application of advanced technology to naval avionics. This study was accomplished as a cooperative venture by members of the Naval Aviation Systems team and over 50 leading firms from the electronics and aerospace industries. The study team also included representatives from the Air Force, Advanced Research Projects Agency, National Institute for Standards and Technology, and the Defense Systems Management College. Their goal was to review emerging technologies, investigate their potential for application to naval avionics, and identify potential cost savings. The Joint Aeronautical Commanders Group (JACG) will use this study as a basis for developing and implementing a better acquisition partnership between the military services and industry. This report is the only comprehensive compilation of today's avionics technology. It is a great reference book that contains easily understandable descriptions of today's technologies, including bus architectures, back planes, processors, software, and just about every aspect of avionics design and development. EVALUATION OF THE UH-1N INSTRUMENT PANEL M.S. Thesis
Lawrence E. Miccolis Sep. 1993 72 p
(AD-A273145) Avail: CASI HC A04/MF A01

This study evaluates the current configuration of the U.S. Marine Corps LJH-IN helicopter instrument panel. Additionally, the alternatives for proposed multifunction display (MFD) symbologies associated with the COMM/NAV Block Upgrade for the UH-IN were evaluated. A survey was administered to 43 LJH-IN operational pilots from both east and west coast squadrons. Pilots were asked to rate instruments and devices currently included on the instrument panel on three factors: criticality, frequency of use, and satisfaction with display. The top ten and bottom ten instruments were identified for each of these three factors; 20 instruments rated high on all three factors while 10 rated low on all three. Several candidates for redesign were identified. Proposed multifunction display symbol sets from the Naval Air Warfare Center Aircraft Division, Warminster (NAWCADWAR), and MIL-STD-1295 (Proposed) were also assessed. Respondents rated symbols for (1) heading scale, present heading, and NAV steering bug (a pointer); (2) airspeed and present airspeed; (3) vertical velocity; (4) attitude, horizon, pitch angle, and aircraft reference; (5) altitude scale, present altitude, and high/low altitude warning; (6) torque; and (7) bank of roll scale, and slip. In general, the NAWCADWAR symbol set was referred. DTIC

An improved jet flap arrangement is provided for producing a pre-swirl at the compressor inlet of a gas turbine engine, in order to enhance engine stability and performance particularly at low-speed off-design conditions. According to the invention, an airflow path is defined between the shroud and hub of the engine for passing air to the compressor entry. A plurality of airfoils extends across the airflow path and upstream of the compressor entry. The airfoils are hollow and communicate with an air inlet in the shroud for communicating with a source of a pressurized gas flow. The airfoils have a leading and a trailing edge relative to the airflow path and a plurality of discrete openings which are closely spaced apart to define an axis extending across the airflow path from the shroud to the hub and spaced a short distance from the trailing edge. These openings form nozzles for discharge of the pressurized gas flow, thereby forming a jet flap across the airflow path for creating a pre-swirl in the airflow path. The airfoils may be struts extending between the shroud and hub in the airflow path. Author (CISTI)

COUNTERROTATING AIRCRAFT PROPULSOR BLADES Patent
Joey L. Nelson, inventor (to General Electric Co.), Sidney B. Elston, inventor (to General Electric Co.), and Wu-Yang Tseng, inventor (to General Electric Co.) 22 Jun. 1993 42 p
(CA-Patent-1-319-357; Int-Patent-Class-B64C-11/20; Int-Patent-Class-B64C-11/48; CTN-94-60924) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A swept propeller blade is provided which is comprised of composite materials having the strength and airfoil configuration to provide an efficient blade for a counterrotating propeller system having highly swept, wide chord, thin blades for operating at transonic and supersonic speeds. A typical blade of the propulsor system includes an airfoil section having a tip end, a root end, and first and second surfaces between the ends intersecting in a convex leading edge and a concave trailing edge. Each surface is formed from a blade shell made of a plurality of angle plied composite laminates bonded together. A metallic blade spar is interposed between the first and second shells and is bonded to the shells for connecting the shell surfaces to the root end and for stiffening the blade. Foam filled airfoil cavities are created interposed between the first and second shells for decreasing the blade weight. A metallic plate sheath is bonded to the leading edge for preventing erosion and providing lightning protection. Counterweights in the blade spar fore and aft of the spar dovetail are adjustable to provide static balancing of the blade in radial and chord-wise directions. A polyurethane film is applied to the outer blade surface for protection. Author (CISTI)

TRANSIENT EJECTOR ANALYSIS (TEA) CODE USER'S GUIDE
Colin K. Drummond Dec. 1993 51 p
(RTOP 505-62-30)

(NASA-TM-106310; E-8050; NAS 1.15:106310) Avail: CASI HC A04/MF A01

A FORTRAN computer program for the semi analytic prediction of unsteady thrust augmenting ejector performance has been developed, based on a theoretical analysis for ejectors. That analysis blends classic self-similar turbulent jet descriptions with control-volume mixing region elements. Division of the ejector into an inlet, diffuser, and mixing region allowed flexibility in the modeling of the physics for each region. In particular, the inlet and diffuser analyses are simplified by a quasi-steady-analysis, justified by the assumption that pressure is the forcing function in those regions. Only the mixing region is assumed to be dominated by viscous effects. The present work provides an overview of the code structure, a description of the required input and output data file formats, and the results for a test case. Since there are limitations to the code for applications outside the bounds of the test case, the user should consider TEA as a research code (not as a production code), designed specifically as an implementation of the proposed ejector theory. Program error flags are discussed, and some diagnostic routines are presented. Author (revised)

HOLOGRAPHIC TESTING OF COMPOSITE PROPFANS FOR A CRUISE MISSILE WIND TUNNEL MODEL

Christopher J. Miller Jan. 1994 41 p

(RTOP 535-03-10)

(NASA-TM-105271; E-8203; NAS 1.15:105271) Avail: CASI HC A03/MF A01

Each of the approximately 90 composite propfan blades constructed for a 55 percent scale cruise missile wind tunnel model were holographically tested to obtain natural frequencies and mode shapes. These data were used not only for quality assurance, but also to select sets of similar blades for each blade row. Presented along with the natural frequency data is a description of a computer-based image processing system developed to supplement the photographic based system for holographic image analysis and storage. The new system is quicker and cheaper, the holograms are indexed better, and several engineers can access the data simultaneously. The only negative effect is a slight reduction in image resolution, which does not influence the end use. Author (revised)

A RANDOM DISTRIBUTION REACTING MIXING LAYER MODEL Final Report

Richard A. Jones Jan. 1994 17 p

(Contract NCC3-213; RTOP 505-62-52)

(NASA-CR-194445; E-8315; NAS 1.26:194445) Avail: CASI HC A03/MF A01

A methodology for simulation of molecular mixing and the resulting velocity and temperature fields has been developed. The ideas are applied to the flow conditions present in the NASA Lewis Planar Reacting Shear Layer (PRSL) facility, and results compared to experimental data. A gaussian transverse turbulent velocity distribution is used in conjunction with a linearly increasing time scale to describe the mixing of different regions of the flow. Equilibrium reaction calculations are then performed on the mix to arrive at a new species composition and temperature. Velocities are determined through summation of momentum contributions. The analysis indicates a combustion efficiency of the order of 80 percent for the reacting mixing layer, and a turbulent Schmidt number of 2/3. The success of the model is attributed to the simulation of large-scale transport of fluid. The favorable comparison shows that a relatively quick and simple PC calculation is capable of simulating the basic flow structure in the reacting and non-reacting shear layer present in the facility given basic assumptions about turbulence properties. THE RB211: THE FIRST 25 YEARS

Philip Ruffles 1992 33 p Presented at the 31st Short Brothers Commemorative Lecture to Royal Aeronautical Society, Queens University, Belfast, Ireland, 16 Jan. 1992 Limited Reproducibility: More than 20% of this document may be affected by poor print

(PNR-90977; MISC-2665; ETN-93-93707) Copyright Avail: Issuing Activity (European Space Agency (ESA))

The development of the RB211 high bypass turbofan engine is reviewed giving details on its early problems and inherent strengths, the dramatic evolution of the design and finally, how the engine family will address the future market. The RB211-22 first entered service in the L1011 Tristar with Eastern Airline in 1972. Now, twenty years later, the RB211 has been developed into an outstanding family of engines; the -524 for the Boeing 747 and 767, the smaller -535 on the Boeing 757 and the latest and most powerful Trent family, for the new Airbus A330, Boeing 777 and McDonnell Douglas MD-12 aircraft. The RN211 has now gained over 40 million hours experience with 64 customers and its evolutionary development has given rise to many unique innovations in design and manufacturing to meet the requirements of the customer. EVALUATION OF REDUCING GAS TURBINE EMISSIONS THROUGH HYDROGEN-ENHANCED STEAM-INJECTED COMBUSTION Final Report, Nov. 1991 - Apr. 1993

J. R. Maughan, J. H. Bowen, S. G. Kimura, D. H. Cooke, and G. Joshi Apr. 1993 168 p Prepared in cooperation with Pullman Kellogg, Houston, TX. Sponsored by Gas Research Inst., Chicago, IL Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract GRI-5091-293-2188)

(PB94-109873; GRI-93/0272) Avail: Issuing Activity (National Technical Information Service (NTIS))

The potential for reducing emissions from gas turbines by injecting steam for NO(x) control and hydrogen for CO control is evaluated through laboratory-scale combustion experiments. Results showed that hydrogen addition into a steam-injected diffusion combustor at hydrogen/fuel molar ratios of approximately 20% was associated with somewhat increased NO(x) production and reduced CO emissions. Both effects are attributed to an increase in the local stoichiometric flame temperature. However, the decrease in CO was greater than the increase in NO(x), resulting in a net emissions benefit, or a shifting of the NO(x)-CO curve toward the origin. Consequently, a greater range of NO(x)/CO emissions targets could be achieved when hydrogen was available. NTIS

CFD ASSESSMENT OF ORIFICE ASPECT RATIO AND MASS FLOW RATIO ON JET MIXING IN RECTANGULAR DUCTS

D. B. Bain (Computational Fluid Dynamics Research Corp., Huntsville, AL.), C. E. Smith (Computational Fluid Dynamics Research Corp., Huntsville, AL.), and J. D. Holdeman Jan. 1994 27 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA Original contains color illustrations

(Contract NAS3-25967)

(NASA-TM-106434; E-8276; NAS 1.15:106434; AIAA Paper 94-0218)

Avail: CASI HC A03/MF A01; 8 functional color pages

Isothermal CFD analysis was performed on axially opposed rows of jets mixing with cross flow in a rectangular duct. Laterally, the jets' centerlines were aligned with each other on the top and bottom walls. The focus of this study was to characterize the effects of orifice aspect ratio and jet-to-mainstream mass flow ratio on jet penetration and mixing. Orifice aspect ratios (L/W) of 4-to-1, 2-to-1, and 1-to-1, along with circular holes, were parametrically analyzed. Likewise, jet-to-mainstream mass flow ratios (MR) of 2.0, 0.5, and 0.25 were systematically investigated. The jet-to-mainstream momentum-flux ratio (J) was maintained at 36 for all cases, and the orifice spacing-to-duct height (S/H) was varied until optimum mixing was attained for each configuration. The numerical results showed that orifice aspect ratio (and likewise orifice blockage) had little effect on jet penetration and mixing. Based on mixing characteristics alone, the 4-to-1 slot was comparable to the circular orifice. The 4-to-1 slot has a smaller jet wake which may be advantageous for reducing emissions. However, the axial length of a 4-to-1 slot may be prohibitively long for practical application, especially for MR of 2.0. The jet-to-mainstream mass flow ratio had a more significant effect on jet penetration and mixing. For a 4-to-1 aspect ratio orifice, the design correlating parameter for optimum mixing (C = (S/H)(sq. root J)) varied from 2.25 for a mass flow ratio of 2.0 to 1.5 for a mass flow ratio of 0.25. (NASA-TM-4532; H-1946; NAS 1.15:4532; AIAA Paper 93-3764)
Copyright Avail: CASI HC A03/MF A01

The application of an adaptive real-time measurement-based performance optimization technique is being explored for a future flight research program. The key technical challenge of the approach is parameter identification, which uses a perturbation-search technique to identify changes in performance caused by forced oscillations of the controls. The controls on the NASA F-15 highly integrated digital electronic control (HIDEC) aircraft were perturbed using inlet cowl rotation steps at various subsonic and supersonic flight conditions to determine the effect on aircraft performance. The feasibility of the perturbation-search technique for identifying integrated airframe-propulsion system performance effects was successfully shown through flight experiments and postflight data analysis. Aircraft response and control data were analyzed postflight to identify gradients and to determine the minimum drag point. Changes in longitudinal acceleration as small as 0.004 g were measured, and absolute resolution was estimated to be 0.002 g or approximately 50 lbf of drag. Two techniques for identifying performance gradients were compared: a least-squares estimation algorithm and a modified maximum likelihood estimator algorithm. A complementary filter algorithm was used with the least squares estimator. Author

WING MOUNTED UNDUCTED FAN ENGINE Patent

A. P. Adamson, inventor (to General Electric Co.) and Wu-Yang Tseng, inventor (to General Electric Co.) 19 Oct. 1993 22 p
(CA-Patent-1323353; Int-Patent-Class-B64D-027/10; Int-Patent-Class-B64D-027/02; CTN-94-60930) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An aircraft propulsion system comprises a pusher type engine including propulsor blades and an engine mounting means which minimizes the two per revolution excitation of the blades due to a wake interaction with the blades. One embodiment of the system is an aircraft engine comprising a plurality of propulsor blades which define an engine disk and a wake interaction zone across the disk having a radial location on the disk, wherein the relative strength of the dynamic loads acting on the propulsor blades is a function of the radial location having at least one relative minimum along the blade length. The location is such that the value of the function is essentially a relative minimum. A more particular embodiment is a wing mounted pusher aircraft engine comprising a plurality of propulsor blades defining an engine disk and a wake interaction zone across the disk having a radial location on the disk wherein the wake is shed from the aircraft wing. The relative strength of the dynamic loads acting on the blades is a function of the radial location, which is such that the value of the function is essentially a relative minimum. Author (CISTI)

GAS TURBINE AND OPERATING METHOD OF THE SAME Patent Application

Susumu Morishita, inventor (to Micromedia Ltd.), Yoshiaki Miyake, inventor (to Micromedia Ltd.), and Seishi Uchida, inventor (to Micromedia Ltd.) 23 Nov. 1992 18 p
(CA-Patent-Appl-SN-2043039; Int-Patent-Class-F02C-007/042; CTN-94-60870) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A gas turbine is characterized by a centrifugal compressor driven by a high pressure turbine and a variable inlet guide vane (VIGV) located at the inlet of the compressor. An axial flow compressor is not provided between the centrifugal compressor and the VIGV. A thrust gas turbine is provided, equipped with a centrifugal compressor which compresses air, a combustor for combustion of fuel using the pressurized air, and a turbine driven to rotate with a part of the energy of the gas produced in the combustor and which drives the compressor; this turbine is characterized by a VIGV at the compressor inlet. A method for operating a gas turbine is also disclosed, characterized in that output is varied by driving the VIGV while keeping the rotation at a high level. According to this invention, it is possible to reduce the flow rate of air taken into an engine so as to reduce the brake horsepower of the engine even at high engine rotation by throttling the VIGV. When the VIGV is opened suddenly, the flow rate increases and the output also increases rapidly; thus the engine output response time is determined almost entirely by the VIGV response time. Thus, an engine with high responsiveness and reliability may be realized according to the invention. Embodiments of the invention include various aircraft engines. CISTI

MIXING CHARACTERISTICS OF DIRECTLY OPPOSED ROWS OF JETS INJECTED NORMAL TO A CROSSFLOW IN A RECTANGULAR DUCT

D. S. Liscinsky (United Technologies Research Center, East Hartford, CT.), B. True (United Technologies Research Center, East Hartford, CT.), and J. D. Holdeman Jan. 1994 12 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA Original contains color illustrations
(Contract NAS3-25954; RTOP 537-02-21)
(NASA-TM-106477; E-8405; NAS 1.15:106477; AIAA Paper 94-0217)
Avail: CASI HC A03/MF A01; 5 functional color pages

An experimental investigation of the mixing of nonreacting opposed rows of inline jets injected perpendicular to a uniform crossflow has been conducted in a rectangular duct. Planar Mie-scattering was used to measure the time-average concentration distribution of the jet fluid in planes perpendicular to the duct axis. Orifice configurations with geometric blockages ranging from 0.59 to 0.89 had similar mixing performance when compared at one-half duct height downstream of injection. Blockage was varied by changing the orifice aspect ratio from 1-to-1 to 1-to-1.5 while maintaining orifice spacing-to-duct height (S/H) at 0.425, jet-to-mainstream mass flow ratio (MR) at 2.0, and jet-to-mainstream momentum-flux ratio (J) at 48. The result indicates that the design correlating expression (at MR = 2) for optimum in line mixing of 2.5 approximately equal to (S/H)(square root of J) is independent of the Webb between adjacent orifices and therefore independent of orifice width. Experimental and numerical results for an orifice aspect ratio 1-to-1 case were in good agreement. The results of a comparison of inline 45 degrees slanted slot and round orifice configuration indicate that in order to obtain equivalent mean concentration distributions at the same J it is necessary to use a smaller S/H for the round orifice configuration. Conclusions about the performance of various orifice shapes can only be obtained from comparison of optimized configurations. Inline jets with different momentum-flux ratios on opposite sides were compared at a constant mass flow ratio. The orifice spacing chosen was previously found to be an optimum configuration when opposing values of J were equal and also an optimum for single side injection. Experimental and empirical results were in good agreement. Author

The objective of the ACES/IPD program is to develop methodologies for incorporating integrated product development principles into the advanced exhaust nozzle development process to insure smooth transition to engineering development products, decreased development time, reduced life cycle costs, and increased system quality. This report documents the activities as part of tasks one and two of the ACES/IPD program. A comprehensive survey of Pratt and Whitney advanced nozzle programs was conducted and lessons learned were extracted to serve as a guide for future advanced technology exhaust system development. [A CONCEPTUAL DESIGN OF AN UNMANNED TEST VEHICLE USING AN AIRBREATHING PROPULSION SYSTEM]
1992 60 p
(Contract NASw-4435)
(NASA-CR-195550; NAS 1.26:195550) Avail: CASI HC A04/MF A01

According to Aviation Week and Space Technology (Nov. 16, 1992), without a redefined approach to the problem of achieving single stage-to-orbit flight, the X-30 program is virtually assured of cancellation. One of the significant design goals of the X-30 program is to achieve single stage to low-earth orbit using airbreathing propulsion systems. In an attempt to avoid cancellation, the NASP Program has decided to design a test vehicle to achieve these goals. This report recommends a conceptual design of an unmanned test vehicle using an airbreathing propulsion system. Author (revised)

TWO-DIMENSIONAL CFD MODELING OF WAVE ROTOR FLOW DYNAMICS
Gerard E. Welch and Rodrick V. Chima Feb. 1994 16 p Presented at the 11th Computational Fluid Dynamics Conference, Orlando, FL, 6-9 Jul. 1993; sponsored by AIAA See also A93-45014
(RTOP 505-62-10)
(NASA-TM-106261; E-8404; NAS 1.15:106261) Avail: CASI HC A03/MF A01

A two-dimensional Navier-Stokes solver developed for detailed study of wave rotor flow dynamics is described. The CFD model is helping characterize important loss mechanisms within the wave rotor. The wave rotor stationary ports and the moving rotor passages are resolved on multiple computational grid blocks. The finite-volume form of the thin-layer Navier-Stokes equations with laminar viscosity are integrated in time using a four-stage Runge-Kutta scheme. Roe's approximate Riemann solution scheme or the computationally less expensive advection upstream splitting method (AUSM) flux-splitting scheme is used to effect upwind-differencing of the inviscid flux terms, using cell interface primitive variables set by MUSCL-type interpolation. The diffusion terms are central-differenced. The solver is validated using a steady shock/laminar boundary layer interaction problem and an unsteady, inviscid wave rotor passage gradual opening problem. A model inlet port/passage charging problem is simulated and key features of the unsteady wave rotor flow field are identified. Lastly, the medium pressure inlet port and high pressure outlet port portion of the NASA Lewis Research Center experimental divider cycle is simulated and computed results are compared with experimental measurements. The model accurately predicts the wave timing within the rotor passages and the distribution of flow variables in the stationary inlet port region. Author (revised)

EFFECT OF POWER SYSTEM TECHNOLOGY AND MISSION REQUIREMENTS ON HIGH ALTITUDE LONG ENDURANCE AIRCRAFT Final Report
Anthony J. Colozza Feb. 1994 22 p
(Contract NAS3-25266; RTOP 537-10-20)
(NASA-CR-194455; E-8408; NAS 1.26:194455) Avail: CASI HC A03/MF A01

An analysis was performed to determine how various power system components and mission requirements affect the sizing of a solar powered long endurance aircraft. The aircraft power system consists of photovoltaic cells and a regenerative fuel cell. Various characteristics of these components, such as PV cell type, PV cell mass, PV cell efficiency, fuel cell efficiency, and fuel cell specific mass, were varied to determine what effect they had on the aircraft sizing for a given mission. Mission parameters, such as time of year, flight altitude, flight latitude, and payload mass and power, were also altered to determine how mission constraints affect the aircraft sizing. An aircraft analysis method which determines the aircraft configuration, aspect ratio, wing area, and total mass, for maximum endurance or minimum required power based on the stated power system and mission parameters is presented. The results indicate that, for the power system, the greatest benefit can be gained by increasing the fuel cell specific energy. Mission requirements also substantially affect the aircraft size. By limiting the time of year the aircraft is required to fly at high northern or southern latitudes, a significant reduction in aircraft size or increase in payload capacity can be achieved. A COMPARISON OF TWO MULTI-VARIABLE INTEGRATOR WINDUP PROTECTION SCHEMES Final Report
Duane Mattern Dec. 1993 11 p Presented at the 1993 AIAA Guidance, Navigation, and Control Conference, Monterey, CA, 9-11 Aug. 1993; sponsored by AIAA See also A93-51404
(Contract NAS3-25266; RTOP 505-62-50)

Avail: CASI HC A03/MF A01

Two methods are examined for limit and integrator wind-up protection for multi-input, multi-output linear controllers subject to actuator constraints. The methods begin with an existing linear controller that satisfies the specifications for the nominal, small perturbation, linear model of the plant. The controllers are formulated to include an additional contribution to the state derivative calculations. The first method to be examined is the multi-variable version of the single-input, single-output, high gain, Conventional Anti-Windup (CAW) scheme. Except for the actuator limits, the CAW scheme is linear. The second scheme to be examined, denoted the Modified Anti-Windup (MAW) scheme, uses a scalar to modify the magnitude of the controller output vector while maintaining the vector direction. The calculation of the scalar modifier is a nonlinear function of the controller outputs and the actuator limits. In both cases the constrained actuator is tracked. These two integrator windup protection methods are demonstrated on a turbofan engine control system with five measurements, four control variables, and four actuators. The closed-loop responses of the two schemes are compared and contrasted during limit operation. The issue of maintaining the direction of the controller output vector using the Modified Anti-Windup scheme is discussed and the advantages and disadvantages of both of the IWP methods are presented. DETERMINATION OF THE STABILITY AND CONTROL DERIVATIVES OF THE NASA F/A-18 HARV USING FLIGHT DATA Contractor Report, 15 May - 15 Dec. 1993
Marcello R. Napolitano and Joelle M. Spagnuolo 15 Dec. 1993 123 p
(Contract NCC2-759)
(NASA-CR-194838; NAS 1.26:194838) Avail: CASI HC A06/MF A02

This report documents the research conducted for the NASA-Ames Cooperative Agreement No. NCC 2-759 with West Virginia University. A complete set of the stability and control derivatives for varying angles of attack from 10 deg to 60 deg were estimated from flight data of the NASA F/A-18 HARV. The data were analyzed with the use of the pEst software which implements the output-error method of parameter estimation. Discussions of the aircraft equations of motion, parameter estimation process, design of flight test maneuvers, and formulation of the mathematical model are presented. The added effects of the thrust vectoring and single surface excitation systems are also addressed. The results of the longitudinal and lateral directional derivative estimates at varying angles of attack are presented and compared to results from previous analyses. The results indicate a significant improvement due to the independent control surface deflections induced by the single surface excitation system, and at the same time, a need for additional flight data especially at higher angles of attack. (Contract NASw-4435)
(NASA-CR-195488; NAS 1.26:195488) Avail: CASI HC A04/MF A01

The purpose of this project is to provide a detail design for the cockpit control system of the Viper PFT. The statement of work for this project requires provisions for control of the ailerons, elevator, rudder, and elevator trim. The system should provide adjustment for pilot stature, rigging, and maintenance. MIL-STD-1472 is used as a model for human factors criterion. The system is designed to the pilot limit loading outlined in FAR part 23.397. The general philosophy behind this design is to provide a simple, reliable control system which will withstand the daily abuse that is experienced in the training environment without excessive cost or weight penalties. FEEDBACK CONTROL LAWS FOR HIGHLY MANEUVERABLE AIRCRAFT Annual Report, 1 Feb. 1993 - 31 Jan. 1994
William L. Garrard and Gary J. Balas 10 Mar. 1994 7 p
(Grant NAG1-1380)
(NASA-CR-195195; NAS 1.26:195195) Avail: CASI HC A02/MF A01

During the first half of the year, the investigators concentrated their efforts on completing the design of control laws for the longitudinal axis of the HARV. During the second half of the year they concentrated on the synthesis of control laws for the lateral-directional axes. The longitudinal control law design efforts can be briefly summarized as follows. Longitudinal control laws were developed for the HARV using mu synthesis design techniques coupled with dynamic inversion. An inner loop dynamic inversion controller was used to simplify the system dynamics by eliminating the aerodynamic nonlinearities and inertial cross coupling. Models of the errors resulting from uncertainties in the principal longitudinal aerodynamic terms were developed and included in the model of the HARV with the inner loop dynamic inversion controller. This resulted in an inner loop transfer function model which was an integrator with the modeling errors characterized as uncertainties in gain and phase. Outer loop controllers were then designed using mu synthesis to provide robustness to these modeling errors and give desired response to pilot inputs. Both pitch rate and angle of attack command following systems were designed. The following tasks have been accomplished for the lateral-directional controllers: inner and outer loop dynamic inversion controllers have been designed; an error model based on a linearized perturbation model of the inner loop system was derived; controllers for the inner loop system have been designed, using classical techniques, that control roll rate and Dutch roll response; the inner loop dynamic inversion and classical controllers have been implemented on the six degree of freedom simulation; and lateral-directional control allocation scheme has been developed based on minimizing required control effort. REMOTE VIBRATION MEASUREMENTS AT A SUD AVIATION ALOUETTE 3 HELICOPTER WITH A CW CO2-LASER SYSTEM
H. E. Boetz 28 Sep. 1993 51 p
(AD-A273818; FEL-93-A183; TDCK-TD93-2777) Avail: CASI HC A04/MF A01

This report describes an experiment with a helicopter to quantify the performance of our experimental multifunctional CO2-laser heterodyne detection system as a vibration detection instrument. The laser system emitted a beam with a diameter of 35 mm with a divergence of 0.5 mrad and a continuous output of 0.4 Watt. The purpose of our measurements was to measure the vibration spectra of a helicopter from the Dutch Air Force at distances between 0.5 to 6 km at various aspect angles. Vibration detection with the help of lasers might prove important for classification of targets. Especially helicopters are of interest because of the typical constant rotor speeds and fixed speed-ratio's between the tail-and main rotor (T/R-ratio) and other characteristics of the spectra. The obtained spectral components are compared with maintenance (rotortuning) frequency measurements done at the airbase with accelerometers. The results are in accordance with each other. The rotor frequencies were determined at all positions of the helicopter. Depending on the place where the laser beam hits the target, the amplitudes of the spikes in the frequency spectrum may vary significantly. With an Advantest R9211C FFT spectrum analyzer, a measurement will take at least one second, yielding a recognizable spectrum at distances of the helicopter up to 4 km. DTIC

FLIGHT CONTROLLER DESIGN USING MIXED H2/H INFINITY OPTIMIZATION WITH A SINGULAR H INFINITY CONSTRAINT M.S. Thesis
James P. Luke Dec. 1993 135 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273831; AFIT/GAE/ENY/93D-21) Avail: CASI HC A07

This thesis explores the effectiveness of mixed H2/H Infinity optimal control design applied to a realistic flight control problem. The application used by this thesis is a single input single output problem dealing with a normal acceleration command following model of the AFTI F-16. The mixed H2/H Infinity control problem is broken into its component H2 and H Infinity parts; the H2 part is formulated as an LQG problem, and a weight is applied to system sensitivity in the H Infinity problem to obtain tracking performance. The sensitivity weight in the underlying H Infinity part results in a singular constraint on the mixed problem. A newly-developed numerical technique is applied and solutions are obtained for controllers of order equal to, first, the order of the underlying H2 problem and, second, the order of the underlying H Infinity problem. Performance characteristics of these controllers are compared to controllers designed using the more-conventional LQG/LTR design method. The results indicate the potential for controllers obtained through mixed H2/H Infinity optimization to provide excellent performance and robustness characteristics at orders less than those obtained through LQG/LTR. Since this conclusion grows in significance when applied to multiple input multiple output (MIMO) problems, a three input, five output example is introduced and the underlying H2 and H Infinity problems for two solution approaches are formulated. FLOW QUALITY STUDIES OF THE NASA LEWIS RESEARCH CENTER ICING RESEARCH TUNNEL DIFFUSER

E. Allen Arrington (Sverdrup Technology, Inc., Brook Park, OH.), Mark T. Pickett, and David W. Sheldon Jan. 1994 18 p
(RTOP 505-62-84)
(NASA-TM-106311; E-8051; NAS 1.15:106311) Avail: CASI HC A03/MF A01

The purpose was to document the airflow characteristics in the diffuser of the NASA Lewis Research Center Icing Research Tunnel and to determine the effects of vortex generators on the flow quality in the diffuser. The results were used to determine how to improve the flow in this portion of the tunnel so that it can be more effectively used as an icing test section and such that overall tunnel efficiency can be improved. The demand for tunnel test time and the desire to test models that are too large for the test section were two of the drivers behind this diffuser study. For all vortex generator configurations tested, the flow quality was improved.

PERFORMANCE OF PREFABRICATED GEOCOMPOSITE SUBDRAINAGE SYSTEM IN AN AIRPORT RUNWAY Final Report

Barry J. Dempsey Oct. 1993 80 p
(Contract DTFAC1-87-Z-02015)
(DOT/FAA/RD-93/23) Avail: CASI HC A05/MF A01

A Prefabricated Geocomposite Subdrainage (PGS) system installed in Runway O9-27 at Kewanee Municipal Airport in 1985 was evaluated. The study demonstrated that a PGS system could be installed within the active runway area at a distance of 12.5 ft on either side of the centerline. There were no problems with settlement or distresses along the installation location. Subdrainage outflow measurements indicated that 25 percent to 45 percent of the rainfall water infiltrated the pavement and passed through the PGS system. Subdrainage outflows varied but a maximum outflow of over 1700 gal/hr was measured during the study. It was observed that water flow from the pavement joints and cracks ceased once the PGS system was installed. The FWD data indicated that the subgrade soil beneath Runway 09-27 ranged from less than 1 ksi to generally 3 ksi. Although there was some improvement in subgrade strength during the study period it was not possible to conclude that subdrainage was totally responsible for this improvement. There was an indication from the data analysis that there could be some raveling in the lower half of the full-depth asphalt concrete layer. The PCI study conducted on Runway 09-27 provided results from 1981 to 1990. The PCI ratings obtained after installation of the PGS system in 1985 indicated the possibility of some overall improvement in pavement performance. Visual observations indicated that surface seepage of water and frost heave problems did not occur again after installation of subdrainage. Visual inspection in January 1993 indicated there was no evidence of longitudinal reflective cracking in the 3 in. asphalt concrete overlay, that was placed during the summer 1990, in the area above the PCS system. It would appear that the PGS system is continuing to function properly and that Runway 09-27 at Kewanee Municipal Airport is performing very well.

DEPLOYABLE VIDEO CONFERENCE TABLE Patent

Marc M. Cohen, inventor (to NASA) and Peter Lissol, inventor (to NASA) 16 Nov. 1993 17 p Filed 3 Feb. 1992
(NASA-Case-ARC-11950-1; US-Patent-5,261,735; US-Patent-Appl-SN-829839; US-Patent-Class-312-282; US-Patent-Class-108-3; US-Patent-Class-108-59; Int-Patent-Class-A47B-77/10) Avail: US Patent and Trademark Office

A deployable table is presented. The table is stowed in and deployed from a storage compartment based upon a non-self rigidizing, 4-hinge, arch support structure that folds upon itself to stow and that expands to deploy. The work surfaces bypass each other above and below to allow the deployment mechanism to operate. This assembly includes the following: first and second primary pivot hinges placed at the opposite ends of the storage compartment; first and second lateral frame members with proximal ends connected to the first and second pivot hinges; a medial frame member offset from and pivotally connected to distal ends of the first and second members through third and fourth medial pivot hinges; and left-side, right-side, and middle trays connected respectively to the first, second, and third frame members and being foldable into and out of the storage compartment by articulation of the first, second, third, and fourth joints. At least one of the third and fourth joints are locked to set the first, second, and third frame members in a desired angular orientation with respect to each other. CALIBRATION OF HYPULSE FOR HYPERVELOCITY AIR FLOWS CORRESPONDING TO FLIGHT MACH NUMBERS 13.5, 15, AND 17

John Calleja and Jose Tamagno Dec. 1993 60 p
(Contract NAS1-18450; RTOP 505-70-62-09)
(NASA-CR-191578; TR-335; NAS 1.26:191578) Avail: CASI HC A04/MF A01

A series of air calibration tests were performed in GASL's HYPULSE facility in order to more accurately determine test section flow conditions for flows simulating total enthalpies in the Mach 13 to 17 range. Present calibration data supplements previous data and includes direct measurement of test section pitot and static pressure, acceleration tube wall pressure and heat transfer, and primary and secondary incident shock velocities. Useful test core diameters along with the corresponding free-stream conditions and usable testing times were determined. For the M13.5 condition, in-stream static pressure surveys showed the temporal and spacial uniformity of this quantity across the useful test core. In addition, finite fringe interferograms taken of the free-stream flow at the test section did not indicate the presence of any 'strong' wave system for any of the conditions investigated.

AIRPORT PAVEMENT TEST MACHINE DESIGN AND COST STUDY Final Report

Gordon F. Hayhoe, Roy D. McQueen, and Edward H. Guo Oct. 1993 126 p
(Contract DTFA03-89-C-00043)
(DOT/FAA/CT-93/51) Avail: CASI HC A07/MF A02

A design study was conducted to determine the feasibility of constructing and operating a test machine for performing accelerated airport pavement tests. The proposed design for the test machine satisfies the requirements of a comprehensive set of specifications formulated and developed by a government/industry working group. The primary purpose of the tests to be conducted with the test machine is to provide pavement response and performance data to be used in the development of new procedures for designing pavements for the next generation of large civil transport aircraft. The proposed test machine design allows for test pavements 60 feet wide by 900 feet long. Maximum load capacity is twelve wheels operating at 75,000 pounds each, for a maximum applied load of 900,000 pounds. Test speeds are 5 mph for normal testing and a maximum of 15 mph for special studies. Cost estimates were made for designing, constructing, and operating the test machine. The total initial cost required to design and construct the machine was estimated to be $15,000,000. Maximum annual operating costs after commissioning were estimated to be $2,300,000. Test pavement reconstruction accounts for $1,500,000 (65%) of the estimated annual operating cost. Author

SAFETY GUIDELINES FOR THE OPERATION OF THE DREO 10 m EMP SIMULATOR DREMPS

C. L. Gardner, J. S. Seregelyi, and P. Sevat Jan. 1993 38 p
(DREO-TN-93-5; CTN-94-60913) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

A large facility was recently completed which simulates the electromagnetic pulse (EMP) that would be produced by the explosion of a nuclear weapon outside the atmosphere. This EMP represents a threat to military electronic systems. To generate this EMP, a high voltage (600 kV) pulse generator is used. As with all high voltage equipment, the EMP simulator contains inherent hazards. Operators of the facility must follow strict safety precautions in its operation and maintenance. An outline is provided giving details of the hazards that may exist as well as procedures that must be followed to ensure safe operation and maintenance of the facility. Author (CISTI)

TEM CELL SAFETY REPORT

J. S. Seregelyi and C. Gardner Apr. 1993 17 p
(DREO-TN-93-9; CTN-94-60919) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

In order to test the susceptibility of a piece of equipment to an electromagnetic pulse (EMP), an accurate electric and magnetic field is required. One means of generating such fields is with a transverse electromagnetic (TEM) cell. This device is essentially a square coaxial line with known field properties. Although the design of the Defence Research Establishment Ottawa's EMP TEM cell includes devices for the protection of both operator and machine, safe use of the system depends upon the operator. The potential hazards of this TEM cell system are described and appropriate precautions are recommended to be followed during operation and maintenance. Safe and reliable operation can be expected if the machine is operated by personnel acquainted with its function and who follow the procedures outlined. Author (CISTI)

COMBINED 1991 AND 1992 ROBINSON-22B (R-22) PARKING TEST RESULTS Technical Report, Sep. 1991 - Oct. 1992

Rosanne M. Weiss Sep. 1993 71 p
(AD-A273550; DOT/FAA/CT-TN93/6) Avail: CASI HC A04/MF A01

Tests were conducted in the fall of 1991 and 1992 at the Federal Aviation Administration (FAA) Technical Center to examine issues regarding rotor tip clearances for parking areas at heliports. These tests were initiated as a follow-on to previous parking tests documented in DOT/FAA/CT-TN88/30, 'Heliport Surface Maneuvering Test Results,' and DOT/FAA/CT-TN/92/1, 'Helicopter Nighttime Parking Test Results-UH-I.' Since those tests utilized a medium-size helicopter with a rotor diameter of 48 feet, similar tests were requested using a smaller helicopter with a rotor diameter of less than 30 feet. The results of these follow-on parking tests which used a Robinson-22B (R-22) helicopter are documented. Over 480 maneuvers were conducted at the FAA Technical Center's National Concepts Development and Demonstration Heliport/Vertiport, Atlantic City International Airport, NJ. All were conducted under head, tail, and crosswind conditions, both with and without an obstacle on the helipad. Pilot subjective data, in reference to these maneuvers, were collected via post-maneuver and post-flight questions. Data collection and analysis methodology and objective, as well as subjective issues, are discussed. Statistical and graphical analysis of pilot performance and perception data are provided. Conclusions are drawn about considerations that must be given to parking clearance criteria at heliports. DTIC

In supporting fundamental flight simulation techniques as a part of academic research, the Delft University of Technology has recently launched the BARESIM program, the development of an advanced general-purpose vehicle simulator facility. The Structures and Materials Group of the faculty of Aerospace Engineering participates in the program by the design and construction of the simulator platform. The report describes the results of a pre-design study of the platform structure, which is performed as a semester project in the scope of the European student-exchange-program ERASMUS between the Munich University of Technology and the Delft University of Technology. SYSTEM FOR AUTOMATIC TRANSPORTATION OF AIRCRAFT ON THE GROUND Patent

Nils-Eric Anderberg, inventor (to Micromedia Ltd.) 21 Sep. 1993 16 p
(CA-Patent-1-322-361; Int-Patent-Class-B64F-001/22; CTN-94-60933) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A system is provided for automatically transporting aircraft on the ground to a precise parking position. The system of the invention satisfies the requirements of environmental friendliness, reliability, flexibility, security, and accuracy of positioning, and can be adapted to all types of aircraft arriving at civil airports. The system is operated by remote means, such as by radio signals, with only minor assistance of ground personnel. The system can be preprogrammed so that it can park a heavy airliner with an accuracy down to one mm adjacent to, for example, a passenger loading device or in the position outside the gate from which the aircraft is to taxi by means of its own engines. The system of the invention consists of a carriage which catches and locks at least one wheel of the aircraft, preferably the nose wheel, and which is drivable back and forth along a guide means arranged on or in the ground. Each end of the guide means is provided with a capstan and a towing rope runs between both capstans. A computer control and monitoring system ensures that start and stop operations are performed properly and smoothly so as to put minimum strain on the landing gear of the aircraft. CISTI

TEMPERATURE MEASUREMENT USING INFRARED IMAGING SYSTEMS DURING TURBINE ENGINE ALTITUDE TESTING

Maureen E. Burns Feb. 1994 23 p
(RTOP 505-62-84)
(NASA-TM-105871; E-7336; NAS 1.15:105871) Avail: CASI HC A03/MF A01

This report details the use of infrared imaging for temperature measurement and thermal pattern determination during simulated altitude engine testing in the NASA Lewis Propulsion Systems Laboratory. Three identical argon-cooled imaging systems were installed in the facility exhaust collector behind sapphire windows to look at engine internal surfaces. The report describes the components of each system, presents the specifics of the complicated installation, and explains the operation of the systems during engine testing. During the program, several problems emerged, such as argon contamination system, component overheating, cracked sapphire windows, and other unexplained effects. This report includes a summary of the difficulties as well as the solutions developed. The systems performed well, considering they were in an unusually harsh exhaust environment. Both video and digital data were recorded, and the information provided valuable material for the engineers and designers to quickly make any necessary design changes to the engine hardware cooling system. The knowledge and experience gained during this program greatly simplified the installation and use of the systems during later test programs in the facility. The infrared imaging systems have significantly enhanced the measurement capabilities of the facility, and have become an outstanding and versatile testing resource in the Propulsion Systems Laboratory. AUTOMATIC PRESSURE CONTROL SYSTEM FOR THE WRIGHT LABORATORY COMPRESSOR RESEARCH FACILITY M.S. Thesis
Brian J. Hull Dec. 1993 96 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273827; AFIT/GAE/ENY/93D-19) Avail: CASI HC A05

This thesis presents the design of a pressure control system for the Compressor Research Facility (CRF). Using a fluid dynamics model of the CRF, a controller was designed to track commanded test chamber pressure while the test compressor operated at varying speeds. This was accomplished by adjusting CRF inlet valves first with a coarse open-loop gain schedule, then closing the loop with a digital dynamic compensator for fine adjustments. The design was simulated on a digital computer and coded for incorporation into the CRF's current control algorithm. DTIC

CATALOG OF APOLLO EXPERIMENT OPERATIONS
Thomas A. Sullivan Jan. 1994 161 p
(NASA-RP-1317; S-738; NAS 1.61:1317) Avail: CASI HC A08/MF A02

This catalog reviews Apollo mission reports, preliminary science reports, technical crew debriefings, lunar surface operations plans, and various relevant lunar experiment documents, collecting engineering- and operation-specific information by experiment. It is organized by discrete experimental and equipment items emplaced or operated on the lunar surface or at zero gravity during the Apollo missions. It also attempts to summarize some of the general problems encountered on the surface and provides guidelines for the design of future lunar surface experiments with an eye toward operations. Many of the problems dealt with on the lunar surface originated from just a few novel conditions that manifested themselves in various nasty ways. Low gravity caused cables to stick up and get caught on feet, and also made it easy for instruments to tip over. Dust was a problem and caused abrasion, visibility, and thermal control difficulties. Operating in a pressure suit limited a person's activity, especially in the hands. I hope to capture with this document some of the lessons learned from the Apollo era to make the jobs of future astronauts, principle investigators, engineers, and operators of lunar experiments more productive. SPACE TOURISM: A FLIGHT OF FANTASY OR THE NEXT MAJOR SPACE PRODUCT? PAPER SESSION 3: PRODUCTS
Barbara A. Stone 1994 8 p Presented at the Thirty-First Space Congress, Cocoa Beach, FL, 26-29 Apr. 1994
(NASA-TM-109385; NAS 1.15:109385) Avail: CASI HC A02/MF A01

In the euphoria of the early 1980's, a number of creative proposals for nontraditional uses of space were suggested. Taking tourists to space, possibly as early as the 1990's, was one such proposal. While it is now obvious that wherever explorers go, tourists (and hoteliers, restauranteurs, and tour guides) will someday follow. This paper discusses past and present efforts to promote space as a tourist destination. Author (revised)

A conference was held from November 20-22, 1989 at the National Institute of Standards and Technology in Gaithersburg, Maryland for the purpose of discussing methods for reducing the cost of space infrastructure and operations. This was a multidisciplinary group that included invited speakers from both within and outside of the traditional aerospace community. Specific comparison was made in the case of habitats and extravehicular activity with commercially successful undersea operations on earth which operate daily under more severe environmental conditions and with operating budgets on the order of 1/1000 that of orbital analogs. AN EARTH ALBEDO MODEL: A MATHEMATICAL MODEL FOR THE RADIANT ENERGY INPUT TO AN ORBITING SPACECRAFT DUE TO THE DIFFUSE REFLECTANCE OF SOLAR RADIATION FROM THE EARTH BELOW
Thomas W. Flatley and Wendy A. Moore Washington Jan. 1994 33 p
(NASA-TM-104596; Rept-94B00034; NAS 1.15:104596) Avail: CASI HC A03/MF A01

Past missions have shown that the earth's albedo can have a significant effect on the sun sensors used for spacecraft attitude control information. In response to this concern, an algorithm was developed to simulate this phenomenon, consisting of two parts, the physical model of albedo and its effect on the sun sensors. This paper contains the theoretical development of this model, practical operational notes, and its implementation in a FORTRAN subroutine. Author

(Contract NASw-4435)
(NASA-CR-195530; NAS 1.26:195530) Avail: CASI HC A13/MF A03

Two Advanced Design Projects were completed this academic year at Penn State - a mission to the planet Mercury and a mission to the moons of Mars (Phobos and Deimos). At the beginning of the fall semester the students were organized into six groups and given their choice of missions. Once a mission was chosen, the students developed conceptual designs. These designs were then evaluated at the end of the fall semester and combined into two separate mission scenarios. To facilitate the work required for each mission, the class was reorganized in the spring semester by combining groups to form two mission teams. An integration team consisting of two members from each group was formed for each mission team so that communication and exchange of information would be easier among the groups. The types of projects designed by the students evolved from numerous discussions with Penn State faculty and mission planners at the Lewis Research Center Advanced Projects Office. Robotic planetary missions throughout the solar system can be considered valuable precursors to human visits and test beds for innovative technology. For example, by studying the composition of the Martian moons, scientists may be able to determine if their resources may be used or synthesized for consumption during a first human visit. Author

NEAR EARTH ASTEROID RENDEZVOUS
15 Dec. 1992 146 p
(Contract NASw-4435)
(NASA-CR-195518; NAS 1.26:195518) Avail: CASI HC A07/MF A02

The Spacecraft Design Course is the capstone design class for the M.S. in astronautics at the Naval Postgraduate School. The Fall 92 class designed a spacecraft for the Near Earth Asteroid Rendezvous Mission (NEAR). The NEAR mission uses a robotic spacecraft to conduct up-close reconnaissance of a near-earth asteroid. Such a mission will provide information on Solar System formation and possible space resources. The spacecraft is intended to complete a NEAR mission as a relatively low-budget program while striving to gather as much information about the target asteroid as possible. A complete mission analysis and detailed spacecraft design were completed. Mission analysis includes orbit comparison and selection, payload and telemetry requirements, spacecraft configuration, and launch vehicle selection. Spacecraft design includes all major subsystems: structure, electrical power, attitude control, propulsion, payload integration, and thermal control. The resulting spacecraft demonstrates the possibility to meet the NEAR mission requirements using existing technology, 'off-the-shelf' components, and a relatively low-cost launch vehicle. With the downturn of the world economy, the priority of unmanned exploration of the solar system has been lowered. Instead of foregoing all missions to our neighbors in the solar system, a new philosophy of exploration mission design has evolved to insure the continued exploration of the solar system. The 'Discovery-class' design philosophy uses a low cost, limited mission, available technology spacecraft instead of the previous 'Voyager-class' design philosophy that uses a 'do-everything at any cost' spacecraft. The Percival Mission to Mars was proposed by Ares Industries as one of the new 'Discovery-class' of exploration missions. The spacecraft will be christened Percival in honor of American astronomer Percival Lowell who proposed the existence of life on Mars in the early twentieth century. The main purpose of the Percival mission to Mars is to collect and relay scientific data to Earth suitable for designing future manned and unmanned missions to Mars. The measurements and observations made by Percival will help future mission designers to choose among landing sites based on the feasibility and scientific interest of the sites. The primary measurements conducted by the Percival mission include gravity field determination, surface and atmospheric composition, sub-surface soil composition, sub-surface seismic activity, surface weather patterns, and surface imaging. These measurements will be taken from the orbiting Percival spacecraft and from surface penetrators deployed from Mars orbit. The design work for the Percival Mission to Mars was divided among four technical areas: Orbits and Propulsion System, Surface Penetrators, Gravity and Science Instruments, and Spacecraft Structure and Systems. The results for each of the technical areas is summarized and followed by a design cost analysis and recommendations for future analyses. Author (revised)

The potential for excessive plume impingement loads on Space Station

Freedom solar arrays, caused by jet firings from an approaching Space Shuttle, is addressed. An artificial neural network is designed to determine commanded solar array beta gimbal angle for minimum plume loads. The commanded angle would be determined dynamically. The network design proposed involves radial basis functions as activation functions. Design, development, and simulation of this network design are discussed.

The Daisy facility, a 23-degree of freedom large flexible space structure (LFSS) emulator, was made operational for the study of control of such structures. Software was written and tested which enables a researcher to implement control algorithms with a minimal understanding of Daisy's systems. The digital electro-optical position sensor system installed on Daisy was integrated with the control computer to track the position of all of Daisy's ribs. The Daisy structure was successfully brought under complete control in its fully flexible configuration. Two control methods, linear quadratic regulator (LQR) and position derivative, were compared on the basis of actual performance matching that were predicted by a mathematical simulation. For the cases attempted, LQR appeared to be the better method, avoiding an undesirable resonance that the other method could not handle. A tutorial for running Daisy and descriptions of the computer routines are included.

(Contract NAS8-36670)
(NASA-CR-193882; NAS 1.26:193882) Avail: CASI HC A07/MF A02

This report describes, using viewgraphs, the Marshall Space Flight Center's Large Space Structures Ground Test Facilities located in building 4619. Major topics include the Active Control Evaluation of Systems (ACES) Laboratory; the Control-Structures Interaction/Controls, Astrophysics, and Structures Experiment in Space (CSI/CASES); Advanced Development Facility; and the ACES Guest Investigator Program.

Part of the curriculum for the seniors at Vanderbilt University in the Mechanical Engineering Program is to take a design class. The purpose of the class is to expose the students to the open ended problems which working engineers are involved with every day. In the past, the students have been asked to work in a variety of projects developed by the professor. This year Vanderbilt was admitted into the Advanced Design Program (ADP) sponsored by the Universities Space Research Association (USRA) and the National Aeronautics and Space Association (NASA). The grant sponsored undergraduate design and research into new and innovative areas in which NASA is involved. The grant sponsors the Teaching Assistant as well as provides monies for travel and other expenses. The design and research of the seniors of the 1992-1993 school year in association with NASA and USRA is documented. Author (revised)

This document establishes a single digital television transmission standard with sufficient versatility to meet a large variety of instrumentation needs for DOD test ranges. Within the framework of the standard, the user can specify transmission rate, horizontal and temporal resolutions, and can determine what picture quality is required for any particular use. DTIC

THE INTERNAL STRUCTURE AND DYNAMICS OF THE RAILGUN PLASMA ARMATURE BETWEEN INFINITELY WIDE ABLATING RAILS
M. H. Frese 1993 98 p Prepared for Los Alamos National Lab, NM
(Contract W-7405-eng-36)
(DE94-001473; LA-Sub-93-176) Avail: CASI HC A05/MF A02 (US Sales Only)

Conventional guns cannot achieve projectile velocities much greater than the sound speed in burned chemical propellants. Plasma armature railguns should not be subject to the same type of velocity limit. However, experiments indicate that there may be some other mechanism which can limit the velocity. A theory that accurately predicts the observed velocity limit could provide the insight necessary to raise or even lift that limit. As yet, there is no theoretical explanation drawn from physical first principles which predicts a limit to the achievable velocity. This report describes the first phase of an effort to use two-dimensional dynamic magnetohydrodynamic (MHD) simulation of the plasma motion in the bore to produce such an explanation. In this phase, MACH2, an Air Force two-dimensional MHD code has been quickly adapted to this problem. The principal goal of this effort was to demonstrate the feasibility and desirability of using MACH2 for railgun armature simulation. However, the simulations of plasma armatures described here are the most sophisticated models of the railgun arc presently available; they show the armature as a dynamic and developing plasma in a way never before seen. The goal could not have been more clearly achieved. DOE

PROJECTILE TRANSVERSE MOTION AND STABILITY IN ELECTROMAGNETIC INDUCTION LAUNCHERS
I. R. Shokair Aug. 1993 24 p
(Contract DE-AC04-94AL-85000)
(DE94-001557; SAND-93-1351) Avail: CASI HC A03/MF A01

The transverse motion of a projectile in an electromagnetic induction launcher is considered. The equations of motion for translation and rotation are derived assuming a rigid projectile and a flyway restoring force per unit length that is proportional to the local displacement. Transverse forces and torques due to energized coils are derived for displaced or tilted projectile elements based on a first order perturbation method. The resulting equations of motion for a rigid projectile composed of multiple elements in a multi-coil launcher are analyzed as a coupled oscillator system of equations and a simple stability condition is derived. The equations of motion are incorporated into the 2-D Slingshot code and numerical solutions for the transverse motion are obtained. For the 20 meter navy launcher parameters, we find that stability is achieved with a flyway spring constant of k is approximately equal to 1 x 10(exp 8) N/sq m. For k is approximately equal to 1.5 x 10(exp 8) N/sq m and sample coil misalignment modeled as a sine wave of 1 mm amplitude at wavelengths of one or two meters, the projectile displacement grows to a maximum of 4 mm. This growth is due to resonance between the natural frequency of the projectile transverse motion and the coil displacement wavelength. This resonance does not persist because of the changing axial velocity. Random coil displacement is also found to cause roughly the same projectile displacement. For the maximum displacement a rough estimate of the transverse pressure is 50 bars. DOE

A COMPARISON OF IN-BORE PROJECTILE MOTION FROM AN ELECTROMAGNETIC RAILGUN VERSUS THAT OF A CONVENTIONAL CANNON BARREL Final Report, Aug. 1992 - May 1993
Lawrence W. Burton Oct. 1993 42 p
(DA Proj. 1L1-62618-AH-80)
(AD-A273473; ARL-TR-295) Avail: CASI HC A03/MF A01

An investigation was undertaken to examine electromagnetic (EM) gun-barrel/projectile interaction. The RASCAL code was used in this study because of its ability to easily manipulate relevant parameters such as gun tube centerline, projectile contact stiffness, and projectile design geometry. This work compares the projectile performance in the 9-MJ EM railgun at the University of Texas Center for Electromechanics (UTCEM) to that in a double-travel conventional gun. This comparison was made by varying the parameters listed above for two projectile designs: the M829 Link round; and a preliminary EM design. It was believed that adoption of this format would identify specific areas of the EM gun-projectile system that excite transverse loading. The results of the analysis are presented. DTIC

APPROXIMATE OPTIMAL GUIDANCE FOR THE ADVANCED LAUNCH SYSTEM
T. S. Feeley and J. L. Speyer Dec. 1993 163 p
(Grant NAG1-1090; RTOP 232-01-04-05)
(NASA-CR-4568; NAS 1.26:4568) Avail: CASI HC A08/MF A02

A real-time guidance scheme for the problem of maximizing the payload into orbit subject to the equations of motion for a rocket over a spherical, non-rotating earth is presented. An approximate optimal launch guidance law is developed based upon an asymptotic expansion of the Hamilton - Jacobi - Bellman or dynamic programming equation. The expansion is performed in terms of a small parameter, which is used to separate the dynamics of the problem into primary and perturbation dynamics. For the zeroth-order problem the small parameter is set to zero and a closed-form solution to the zeroth-order expansion term of Hamilton - Jacobi - Bellman equation is obtained. Higher-order terms of the expansion include the effects of the neglected perturbation dynamics. These higher-order terms are determined from the solution of first-order linear partial differential equations requiring only the evaluation of quadratures. This technique is preferred as a real-time, on-line guidance scheme to alternative numerical iterative optimization schemes because of the unreliable convergence properties of these iterative guidance schemes and because the quadratures needed for the approximate optimal guidance law can be performed rapidly and by parallel processing. Even if the approximate solution is not nearly optimal, when using this technique the zeroth-order solution always provides a path which satisfies the terminal constraints. Results for two-degree-of-freedom simulations are presented for the simplified problem of flight in the equatorial plane and compared to the guidance scheme generated by the shooting method which is an iterative second-order technique. Author (revised)

DESIGN OF AN AIRBORNE LAUNCH VEHICLE FOR AN AIR LAUNCHED SPACE BOOSTER
Chin Chao, Rich Choi, Scott Cohen, Brian Dumont, Mauricius Gibin, Rob Jorden, and Stefan Poth 1993 184 p
(Contract NASw-4435)
(NASA-CR-195534; NAS 1.26:195534) Avail: CASI HC A09/MF A02

A conceptual design is presented for a carrier vehicle for an air launched space booster. This airplane is capable of carrying a 500,000 pound satellite launch system to an altitude over 40,000 feet for launch. The airplane features a twin fuselage configuration for improved payload and landing gear integration, a high aspect ratio wing for maneuverability at altitude, and is powered by six General Electric GE-90 engines. The analysis methods used and the systems employed in the airplane are discussed. Launch costs are expected to be competitive with existing launch systems. Author

GRYPHON: AIR LAUNCHED SPACE BOOSTER
Jun. 1993 346 p
(Contract NASw-4435)
(NASA-CR-195497; NAS 1.26:195497) Avail: CASI HC A15/MF A03

The project chosen for the winter semester Aero 483 class was the design of a next generation Air Launched Space Booster. Based on Orbital Sciences Corporation's Pegasus concept, the goal of Aero 483 was to design a 500,000 pound air launched space booster capable of delivering 17,000 pounds of payload to Low Earth Orbit and 8,000 pounds of payload to Geosynchronous Earth Orbit. The resulting launch vehicle was named the Gryphon. The class of forty senior aerospace engineering students was broken down into eight interdependent groups. Each group was assigned a subsystem or responsibility which then became their field of specialization. Spacecraft Integration was responsible for ensuring compatibility between subsystems. This group kept up to date on subsystem redesigns and informed those parties affected by the changes, monitored the vehicle's overall weight and dimensions, and calculated the mass properties of the booster. This group also performed the cost/profitability analysis of the Gryphon and obtained cost data for competing launch systems. The Mission Analysis Group was assigned the task of determining proper orbits, calculating the vehicle's flight trajectory for those orbits, and determining the aerodynamic characteristics of the vehicle. The Propulsion Group chose the engines that were best suited to the mission. This group also set the staging configurations for those engines and designed the tanks and fuel feed system. The commercial satellite market, dimensions and weights of typical satellites, and method of deploying satellites was determined by the Payloads Group. In addition, Payloads identified possible resupply packages for Space Station Freedom and identified those packages that were compatible with the Gryphon. The guidance, navigation, and control subsystems were designed by the Mission Control Group. This group identified required tracking hardware, communications hardware telemetry systems, and ground sites for the location of the Gryphon's mission control center. The Structures group was responsible for ensuring the structural integrity of the vehicle. Their designs included the payload shroud, payload support structure, exterior hull and engine support struts. The Gryphon's power requirements were determined by the Power/Thermal/Attitude Control Group. This group then selected suitable batteries and other components to meet these requirements. The group also designed heat shielding and cooling systems to ensure subsystem performance. In addition to these responsibilities this group designed the attitude control methods and RCS components for the vehicle. The Aircraft Integration Group was responsible for all aspects of the booster aircraft connection. This included the design of the connection structure and the drop mechanism. This group also designed the vehicle assembly facility and identified possible ground bases for the plane. Author

IMPLEMENTING THE SPACE SHUTTLE DATA PROCESSING SYSTEM WITH THE SPACE GENERIC OPEN AVIONICS ARCHITECTURE
Richard B. Wray and John R. Stovall Jul. 1993 43 p
(Contract NAS9-17900)
(NASA-CR-188254; NAS 1.26:188254; LESC-30753) Avail: CASI HC A03/MF A01

This paper presents an overview of the application of the Space Generic Open Avionics Architecture (SGOAA) to the Space Shuttle Data Processing System (DPS) architecture design. This application has been performed to validate the SGOAA, and its potential use in flight critical systems. The paper summarizes key elements of the Space Shuttle avionics architecture, data processing system requirements and software architecture as currently implemented. It then summarizes the SGOAA architecture and describes a tailoring of the SGOAA to the Space Shuttle. The SGOAA consists of a generic system architecture for the entities in spacecraft avionics, a generic processing external and internal hardware architecture, a six class model of interfaces and functional subsystem architectures for data services and operations control capabilities. It has been proposed as an avionics architecture standard with the National Aeronautics and Space Administration (NASA), through its Strategic Avionics Technology Working Group, and is being considered by the Society of Aeronautic Engineers (SAE) as an SAE Avionics Standard. This architecture was developed for the Flight Data Systems Division of JSC by the Lockheed Engineering and Sciences Company, Houston, Texas. Author

A debris/ice/thermal protection system (TPS) assessment and integrated photographic analysis was conducted for shuttle mission STS-61. Debris inspections of the flight elements and launch pad were performed before and after launch. Icing conditions on the external tank were assessed by the use of computer programs, nomographs, and infrared scanner data during cryogenic loading of the vehicle followed by on-pad visual inspection. High speed photography of the launch was analyzed to identify ice/debris sources and evaluate potential vehicle damage and/or in-flight anomalies. This report documents the ice/debris/TPS conditions and integrated photographic analysis of shuttle mission STS-61, and the resulting effect on the space shuttle program. Author (revised)

FINAL POSTFLIGHT HARDWARE EVALUATION REPORT RSRM-32 (STS-57) Final Report
Greg Nielson Nov. 1993 205 p
(Contract NAS8-38100)
(NASA-CR-193903; NAS 1.26:193903; TWR-64240) Avail: CASI HC A10/MF A03

This document is the final report for the postflight assessment of the RSRM-32 (STS-57) flight set. This report presents the disassembly evaluations performed at the Thiokol facilities in Utah and is a continuation of the evaluations performed at KSC (TWR-64239). The PEEP for this assessment is outlined in TWR-50051, Revision B. The PEEP defines the requirements for evaluating RSRM hardware. Special hardware issues pertaining to this flight set requiring additional or modified assessment are outlined in TWR-64237. All observed hardware conditions were documented on PFOR's which are included in Appendix A. Observations were compared against limits defined in the PEEP. Any observation that was categorized as reportable or had no defined limits was documented on a preliminary PFAR by the assessment engineers. Preliminary PFAR's were reviewed by the Thiokol SPAT Executive Board to determine if elevation to PFAR's was required. Derived from text

FINAL POSTFLIGHT HARDWARE EVALUATION REPORT RSRM-28 (STS-53) Final Report
William David Starrett, Jr. Nov. 1993 285 p
(Contract NAS8-38100)
(NASA-CR-193902; NAS 1.26:193902; TWR-64216) Avail: CASI HC A13/MF A03

The final report for the Clearfield disassembly evaluation and a continuation of the KSC postflight assessment for the RSRM-28 (STS-53) RSRM flight set is presented. All observed hardware conditions were documented on PFOR's and are included in Appendices A through C. Appendices D and E contain the measurements and safety factor data for the nozzle and insulation components. This report, along with the KSC Ten-Day Postflight Hardware Evaluation Report (TWR-64215), represents a summary of the RSRM-28 hardware evaluation. The as-flown hardware configuration is documented in TWR-63638. Disassembly evaluation photograph numbers are logged in TWA-1989. The RSRM-28 flight set disassembly evaluations described were performed at the RSRM Refurbishment Facility in Clearfield, Utah. The final factory joint demate occurred on July 15, 1993. Additional time was required to perform the evaluation of the stiffener rings per special issue 4.1.5.2 because of the washout schedule. The release of this report was after completion of all special issues per program management direction. Detailed evaluations were performed in accordance with the Clearfield PEEP, TWR-50051, Revision A. All observations were compared against limits that are also defined in the PEEP. These limits outline the criteria for categorizing the observations as acceptable, reportable, or critical. Hardware conditions that were unexpected and/or determined to be reportable or critical were evaluated by the applicable team and tracked through the PFAR system. Author (revised)

ANALYSIS AND EFFECTS OF THE ADVANCED SOLID ROCKET MOTOR ON THE SPACE SHUTTLE ELEMENTS Interim Final Report
15 Oct. 1993 44 p
(Contract NAS8-39235)
(NASA-CR-193879; NAS 1.26:193879; RTR-250-01) Avail: CASI HC A03/MF A01

This interim final report summarizes the activities and major accomplishments under NASA/MSFC Contract NAS8-39235 for the initial two year contractual effort beginning October 1, 1991, and ending September 30, 1993. It is not intended as an exhaustive treatment or review of any particular technical issue which was addressed during this two-year period, but does provide an overview of the many induced environment studies and test support activities undertaken by REMTECH and its subcontractors during this two-year period. The initial scope of work has been pursued vigorously through this two-year period by separating the effort into five functional areas. The five functional areas are ascent plume radiation, ascent plume convection, ascent aerodynamic heating, launch stand environments, and reentry heating. A work breakdown structure (WBS) for each functional area was devised to permit nearly autonomous activities within each functional responsibility while maintaining commonality in reporting procedures and cost accounting. The contract was modified 11 times to provide incremental funding and to expand the scope of work. Additional work breakdown structure was incorporated to meet the expanded scope. A contract chronology is provided in Section 2. The initial scope of work, expanded scope, and corresponding WBS designation are described in Section 3. A summary review of major accomplishments is also provided in Section 4 to show the breadth of activities and extent of reporting. Reports, meetings, test activities, and other accomplishments within each functional area are also summarized by WBS heading in the appendices. Derived from text

LIGHTNING TESTS AND ANALYSES OF TUNNEL BOND STRAPS AND SHIELDED CABLES ON THE SPACE SHUTTLE SOLID ROCKET BOOSTER Final Report
William M. Druen Nov. 1993 157 p
(Contract NAS8-36300)
(NASA-CR-193921; NAS 1.26:193921; SI-93-2679) Avail: CASI HC A08/MF A02

The purposes of the tests and analyses described in this report are as follows: (1) determine the lightning current survivability of five alternative changed designs of the bond straps which electrically bond the solid rocket booster (SRB) systems tunnel to the solid rocket motor (SRM) case; (2) determine the amount of reduction in induced voltages on operational flight (OF) tunnel cables obtained by a modified design of tunnel bond straps (both tunnel cover-to-cover and cover-to-motor case);

(3) determine the contribution of coupling to the OF tunnel cables by ground electrical and instrumentation (GEI) cables which enter the systems tunnel from unshielded areas on the surfaces of the motor case; and (4) develop a model (based on test data) and calculate the voltage levels at electronic 'black boxes' connected to the OF cables that run in the systems tunnel. POSTFLIGHT HARDWARE EVALUATION (RSRM-29, STS-54) Final Report
Sep. 1993 37 p
(Contract NAS8-38100)
(NASA-CR-193895; NAS 1.26:193895; TWR-64222) Avail: CASI HC A03/MF A01

This document is the final report for the Clearfield disassembly evaluation and a continuation of the KSC postflight assessment for the RSRM-29 flight set. All observed hardware conditions were documented on PFOR's and are included in Appendices A, B, and C. Appendices D and E contain the measurements and safety factor data for the nozzle and insulation components. This report, along with the KSC Ten-Day Postflight Hardware Evaluation Report (TWR-64221), represents a summary of the RSRM-29 hardware evaluation. Disassembly evaluation photograph numbers are logged in TWA-1990. The RSRM-29 flight set disassembly evaluations described in this document were performed at the RSRM Refurbishment Facility in Clearfield, Utah. The final factory joint demate occurred on September 9, 1993. Detailed evaluations were performed in accordance with the Clearfield PEEP, TWR-50051, Revision A. All observations were compared against limits that are also defined in the PEEP. These limits outline the criteria for categorizing the observations as acceptable, reportable, or critical. Hardware conditions that were unexpected and/or determined to be reportable or critical were evaluated by the applicable CPT and tracked through the PFAR system. Derived from text

DEVELOPMENT OF A NONDESTRUCTIVE VIBRATION TECHNIQUE FOR BOND ASSESSMENT OF SPACE SHUTTLE TILES Final Report
Faissal A. Moslehy Feb. 1994 86 p Original contains color illustrations
(Grant NAG10-117)
(NASA-CR-195163; NAS 1.26:195163) Avail: CASI HC A05/MF A01; 14 functional color pages

This final report describes the achievements of the above titled project. The project is funded by NASA-KSC (Grant No. NAG 10-0117) for the period of 1 Jan. to 31 Dec. 1993. The purpose of this project was to develop a nondestructive, noncontact technique based on 'vibration signature' of tile systems to quantify the bond conditions of the thermal protection system) tiles of Space Shuttle orbiters. The technique uses a laser rapid scan system, modal measurements, and finite element modeling. Finite element models were developed for tiles bonded to both clamped and deformable integrated skin-stringer orbiter mid-fuselage. Results showed that the size and location of a disbonded tile can be determined from frequency and mode shape information. Moreover, a frequency response survey was used to quickly identify the disbonded tiles. The finite element results were compared with experimentally determined frequency responses of a 17-tile test panel, where a rapidscan laser system was employed. An excellent degree of correlation between the mathematical simulation and experimental results was realized. An inverse solution for single-tile assemblies was also derived and is being implemented into a computer program that can interact with the modal testing software. The output of the program displays the size and location of disbond. This program has been tested with simulated input (i.e., finite element data), and excellent agreement between predicted and simulated disbonds was shown. Finally, laser vibration imaging and acoustic emission techniques were shown to be well suited for detecting and monitoring the progressive damage in Graphite/Epoxy composite materials. SPACE TRANSFER VEHICLE CONCEPTS AND REQUIREMENTS. VOLUME 4: SUMMARY OF SPECIAL STUDIES
Sep. 1993 751 p
(Contract NAS8-37856)
(NASA-CR-193918; NAS 1.26:193918; MCR-93-1362-Vol-4) Avail: CASI HC A99/MF A06

Our final report for Phase 1 addressed the future space transportation needs and requirements based on the current assets, at the time, and their evolution through technology/advanced development using a path and schedule that supported the world leadership role of the United States in a responsible and realistic financial forecast. Always, and foremost, the recommendations placed high values on the safety and success of missions both manned and unmanned through a total quality management philosophy at Martin Marietta. The second phase of the STV contract involved the use of Technical Directives (TD) to provide short-term support for specialized tasks as required by the COTR. Three of these tasks were performed in parallel with Phase 1. These tasks were the Liquid Acquisition Experiment (LACE), Liquid Reorientation Experiment (LIRE), and Expert System for Design, Operation, and Technology Studies (ESDOTS). The results of these TD's were reported in conjunction with the Phase 1 Final Report. Cost analysis of existing launch systems has demonstrated a need for a new upper stage that will increase America's competitiveness in the global launch services market. To provide a growth path of future exploration class STV's, near-term low-cost upper stages featuring modularity, portability, scalability, and evolvability must be developed. These recommendations define a program that: leverages ongoing activities to establish a new development environment, develop technologies that benefit the entire life cycle of a system, and result in a scalable hardware platform that provides a growth path to future upper stages. (NASA-TM-106397; E-8224; NAS 1.15:106397; AIAA Paper 94-1101)
Avail: CASI HC A02/MF A01

The NASA Lewis Research Center is developing a multichannel communication signal processing satellite (MCSPS) system which will provide low data rate, direct to user, commercial communications services. The focus of current space segment developments is a flexible, high-throughput, fault tolerant onboard information switching processor. This information switching processor (ISP) is a destination-directed packet switch which performs both space and time switching to route user information among numerous user ground terminals. Through both industry study contracts and in-house investigations, several packet switching architectures were examined. A contention-free approach, the shared memory per beam architecture, was selected for implementation. The shared memory per beam architecture, fault tolerance insertion, implementation, and demonstration plans are described. Author (revised)

ADVANCED TECHNOLOGY FOR A SATELLITE MULTICHANNEL DEMULTIPLEXER/DEMODULATOR Final Report
Irwin J. Abramovitz, Drew E. Flechsig, and Richard M. Matteis, Jr. Jan. 1994 57 p
(Contract NAS3-25865; RTOP 235-01-04)
(NASA-CR-194435; E-8317; NAS 1.26:194435) Avail: CASI HC A04/MF A01

Satellite on-board processing is needed to efficiently service multiple users while at the same time minimizing earth station complexity. The processing satellite receives a wideband uplink at 30 GHz and down-converts it to a suitable intermediate frequency. A multichannel demultiplexer then separates the composite signal into discrete channels. Each channel is then demodulated by bulk demodulators, with the baseband signals routed to the downlink processor for retransmission to the receiving earth stations. This type of processing circumvents many of the difficulties associated with traditional bent-pipe repeater satellites. Uplink signal distortion and interference are not retransmitted on the downlink. Downlink power can be allocated in accordance with user needs, independent of uplink transmissions. This allows the uplink users to employ different data rates as well as different modulation and coding schemes. In addition, all downlink users have a common frequency standard and symbol clock on the satellite, which is useful for network synchronization in time division multiple access schemes. The purpose of this program is to demonstrate the concept of an optically implemented multichannel demultiplexer (MCD). A proof-of-concept (POC) model has been developed which has the ability to receive a 40 MHz wide composite signal consisting of up to 1000 40 kHz QPSK modulated channels and perform the demultiplexing process. In addition a set of special test equipment (STE) has been configured to evaluate the performance of the POC model. The optical MCD is realized as an acousto-optic spectrum analyzer utilizing the capability of Bragg cells to perform the required channelization. These Bragg cells receive an optical input from a laser source and an RF input (the signal). The Bragg interaction causes optical output diffractions at angles proportional to the RF input frequency. These discrete diffractions are optically detected and output to individual demodulators for baseband conversion. Optimization of the MCD design was conducted in order to achieve a compromise between two opposing sources of signal degradation: adjacent channel interference and intersymbol interference. The system was also optimized to allow simple, inexpensive ground stations communications with the MCD. These design goals led to the realization of a POC MCD which demonstrates the demultiplexing function with minimal signal degradation. Performance evaluation results using the STE equipment indicate that the dynamic range of the demultiplexer in the presence of adjacent and multiple channel loading is 40 - 50 dB. Measured bit error rate (BER) probabilities varied from the predicted theoretical results by one dB or less. The performance of the proof-of-concept model indicate that the development of a space qualified optically implemented MCD are feasible. The advantages to such an implementation include reduced size, weight and power and increased reliability when compared with electronic approaches. All of these factors are critical to on-board satellite processors. Further optimization can be conducted which trade ground station complexity and MCD performance to achieve desired system results. EXPERIMENTAL VERIFICATION OF AN ACOUSTIC TELEMETRY LINK BETWEEN AN AURORA AND CFAV QUEST
C. M. McIntyre, A. T. Ashley, J. W. MacDonald, and R. L. G. Whitehorne Feb. 1993 30 p
(DREA-TC-93-304; CTN-94-60917) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

To evaluate airborne sonar concepts operationally on a ship-based system, a mechanism must be developed for transmitting both acoustic and nonacoustic data from an aircraft to the ship. An initial evaluation of an acoustic telemetry link between an Aurora patrol aircraft and the research ship CFAV Quest is presented. The link was designed to transmit continuous, real-time acoustic data from sixteen DIFAR sonobuoys between the Aurora and the Quest. In two recent trials of the acoustic telemetry link system, reliable transmission was obtained out to ranges of 50 nautical miles with a tracking antenna receiving system and to ranges of seven nautical miles with an omnidirectional antenna. In each case, the aircraft was required to fly a dedicated pattern to maintain the link and there were short periods during each pattern that the link was poor due to transmission shadows cast by the aircraft or the ship. The acoustic telemetry link system is described in detail along with an initial evaluation of the operating envelopes currently imposed on the Aurora and the Quest in order to obtain reliable transmission. Recommendations are given for improving the quality and flexibility of the link. Author (CISTI)

BOUNDS AND SIMULATION RESULTS OF 32-ARY AND 64-ARY QUADRATURE AMPLITUDE MODULATION FOR BROADBAND-ISDN VIA SATELLITE
Muli Kifle and Mark Vanderaar (Sverdrup Technology, Inc., Brook Park, OH.) Feb. 1994 14 p
(Contracts NAS3-25266; NAS3-27186; RTOP 235-01-04)
(NASA-TM-106484; E-8470; NAS 1.15:106484) Avail: CASI HC A03/MF A01

Union bounds and Monte Carlo simulation Bit-Error-Rate (BER) performance results are presented for various 32-ary and 64-ary Quadrature Amplitude Modulation (QAM) schemes. Filtered and unfiltered modulation formats are compared for the best packing arrangement in peak power limited systems. It is verified that circular constellations which populate as many symbols as possible at the peak magnitude offer the best performance. For example: a 32-ary QAM scheme based on concentric circles offers about 1.05 dB better peak power improvement at a BER of 10(exp -6) over the scheme optimized for average power using triangular symbol packing. This peak power improvement increases to 1.25 dB for comparable 64-ary QAM schemes. This work serves as a precursor to determine the feasibility of a combined modem/codec that can accommodate Broadband Integrated Services Digital Network (B-ISDN) at a rate of 155.52 Mbps through typical transponder bandwidths of 36 MHz and 54 MHz. LIFE CYCLE COST MODELING OF CONCEPTUAL SPACE VEHICLES Interim Report, Jun. - Dec. 1993
Charles Ebeling 1993 67 p
(Grant NAG1-1327)
(NASA-CR-194813; NAS 1.26:194813) Avail: CASI HC A04/MF A01

This paper documents progress to date by the University of Dayton on the development of a life cycle cost model for use during the conceptual design of new launch vehicles and spacecraft. This research is being conducted under NASA Research Grant NAG-1-1327. This research effort changes the focus from that of the first two years in which a reliability and maintainability model was developed to the initial development of a life cycle cost model. Cost categories are initially patterned after NASA's three axis work breakdown structure consisting of a configuration axis (vehicle), a function axis, and a cost axis. The focus will be on operations and maintenance costs and other recurring costs. Secondary tasks performed concurrent with the development of the life cycle costing model include continual support and upgrade of the R&M model. The primary result of the completed research will be a methodology and a computer implementation of the methodology to provide for timely cost analysis in support of the conceptual design activities. The major objectives of this research are: to obtain and to develop improved methods for estimating manpower, spares, software and hardware costs, facilities costs, and other cost categories as identified by NASA personnel; to construct a life cycle cost model of a space transportation system for budget exercises and performance-cost trade-off analysis during the conceptual and development stages; to continue to support modifications and enhancements to the R&M model; and to continue to assist in the development of a simulation model to provide an integrated view of the operations and support of the proposed system. REAL-TIME DYNAMICS AND CONTROL STRATEGIES FOR SPACE OPERATIONS OF FLEXIBLE STRUCTURES Final Report, 15 Jan. 1992 - 14 Jul. 1993
K. C. Park, K. F. Alvin, and S. Alexander Jul. 1993 72 p
(Grant NAG9-574)
(NASA-CR-194794; NAS 1.26:194794; CU-CSSC-93-16) Avail: CASI HC A04/MF A01

This project (NAG9-574) was meant to be a three-year research project. However, due to NASA's reorganizations during 1992, the project was funded only for one year. Accordingly, every effort was made to make the present final report as if the project was meant to be for one-year duration. Originally, during the first year we were planning to accomplish the following: we were to start with a three dimensional flexible manipulator beam with articulated joints and with a linear control-based controller applied at the joints; using this simple example, we were to design the software systems requirements for real-time processing, introduce the streamlining of various computational algorithms, perform the necessary reorganization of the partitioned simulation procedures, and assess the potential speed-up realization of the solution process by parallel computations. The three reports included as part of the final report address: the streamlining of various computational algorithms; the necessary reorganization of the partitioned simulation procedures, in particular the observer models; and an initial attempt of reconfiguring the flexible space structures. A REVIEW OF WIRING SYSTEM SAFETY IN SPACE POWER SYSTEMS
Mark W. Stavnes and Ahmad N. Hammoud Dec. 1993 8 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, 8-13 Aug. 1993; sponsored by ASC, AIAA, AIChE, ANS, ASME, IEEE, and SAE
(Contract NAS3-25266; RTOP 323-57-4A)
(NASA-CR-194439; E-8291; NAS 1.26:194439) Avail: CASI HC A02/MF A01

Wiring system failures have resulted from arc propagation in the wiring harnesses of current aerospace vehicles. These failures occur when the insulation becomes conductive upon the initiation of an arc. In some cases, the conductive path of the carbon arc track displays a high enough resistance such that the current is limited, and therefore may be difficult to detect using conventional circuit protection. Often, such wiring failures are not simply the result of insulation failure, but are due to a combination of wiring system factors. Inadequate circuit protection, unforgiving system designs, and careless maintenance procedures can contribute to a wiring system failure. This paper approaches the problem with respect to the overall wiring system, in order to determine what steps can be taken to improve the reliability, maintainability, and safety of space power systems. Power system technologies, system designs, and maintenance procedures which have led to past wiring system failures will be discussed. New technologies, design processes, and management techniques which may lead to improved wiring system safety will be introduced. Author

US-Patent-Class-114-227; Int-Patent-Class-E02D-37/00) Avail: US Patent and Trademark Office

A rigid patch body for placing over a damaged portion (hole) of an external wall of a pressurized vessel, such as a space vehicle or a habitat, is discussed. The rigid patch body allows an astronaut to make temporary repairs to the pressurized vessel from the exterior of the vessel, which enables more permanent repairs to be made from the interior of the vessel. The pressure wall patch of the present invention includes a floor surrounded by four side members. Each side member includes a threaded screw for anchoring the patch body to the external wall of the pressurized vessel and a recess in its lower surface for supporting an inflatable bladder for surrounding the damaged portion (hole) of the external wall to seal the area surrounding the damaged portion. This allows the vessel to be repressurized. The floor of the rigid patch body supports a source of gas that is connected to the gas supply valve and a gas supply gauge in communication with the gas supply valve and the inflatable bladder. TELEROBOTIC RENDEZVOUS AND DOCKING VISION SYSTEM ARCHITECTURE Final Report, 11 Aug. 1989

Ben Gravely, Donald Myers, and David Moody 17 Jan. 1992 32 p
(Contract NAS5-30709; SBIR-05.01-2878)
(NASA-CR-191329; NAS 1.26:191329) Avail: CASI HC A03/MF A01

This research program has successfully demonstrated a new target label architecture that allows a microcomputer to determine the position, orientation, and identity of an object. It contains a CAD-like database with specific geometric information about the object for approach, grasping, and docking maneuvers. Successful demonstrations were performed selecting and docking an ORU box with either of two ORU receptacles. Small, but significant differences were seen in the two camera types used in the program, and camera sensitive program elements have been identified. The software has been formatted into a new co-autonomy system which provides various levels of operator interaction and promises to allow effective application of telerobotic systems while code improvements are continuing. MAGNETIC SHIELDING OF INTERPLANETARY SPACECRAFT AGAINST SOLAR FLARE RADIATION Final Report, 1992 - 1993

Franklin H. Cocks and Seth Watkins Jul. 1993 36 p
(Contract NASw-4435)
(NASA-CR-195539; NAS 1.26:195539) Avail: CASI HC A03/MF A01

The ultimate objective of this work is to design, build, and fly a dual-purpose, piggyback payload whose function is to produce a large volume, low intensity magnetic field and to test the concept of using such a magnetic field (1) to protect spacecraft against solar flare protons, (2) to produce a thrust of sufficient magnitude to stabilize low satellite orbits against orbital decay from atmospheric drag, and (3) to test the magsail concept. These all appear to be capable of being tested using the same deployed high temperature superconducting coil. In certain orbits, high temperature superconducting wire, which has now been developed to the point where silver-sheathed high T sub c wires one mm in diameter are commercially available, can be used to produce the magnetic moments required for shielding without requiring any mechanical cooling system. The potential benefits of this concept apply directly to both earth-orbital and interplanetary missions. The usefulness of a protective shield for manned missions needs scarcely to be emphasized. Similarly, the usefulness of increasing orbit perigee without expenditure of propellant is obvious. This payload would be a first step in assessing the true potential of large volume magnetic fields in the US space program. The objective of this design research is to develop an innovative, prototype deployed high temperature superconducting coil (DHTSC) system. Derived from text

NPS ALTERNATE TECHSAT SATELLITE, DESIGN PROJECT FOR AE-4871

1993 110 p
(Contract NASw-4435)
(NASA-CR-195512; NAS 1.26:195512) Avail: CASI HC A06/MF A02

This project was completed as part of AE-4871, Advanced Spacecraft Design. The intent of the course is to provide experience in the design of all the major components in a spacecraft system. Team members were given responsibility for the design of one of the six primary subsystems: power, structures, propulsion, attitude control, telemetry, tracking and control (TT&C), and thermal control. In addition, a single member worked on configuration control, launch vehicle integration, and a spacecraft test plan. Given an eleven week time constraint, a preliminary design of each subsystem was completed. Where possible, possible component selections were also made. Assistance for this project came principally from the Naval Research Laboratory's Spacecraft Technology Branch. Specific information on components was solicited from representatives in industry. The design project centers on a general purpose satellite bus that is currently being sought by the Strategic Defense Initiative. Author (revised)

CONCEPTUAL DESIGN OF A TWO STAGE TO ORBIT SPACECRAFT

Scott C. Armiger, Jennifer S. Kwarta, Kevin B. Horsley, Glenn A. Snow, Eric C. Koe, and Thomas G. Single 4 Mar. 1993 233 p
(Contract NASw-4435)
(NASA-CR-195536; NAS 1.26:195536; ME-ANA-TSTO) Avail: CASI HC A11/MF A03

This project, undertaken through the Advanced Space Design Program, developed a 'Conceptual Design of a Two Stage To Orbit Spacecraft (TSTO).' The design developed utilizes a combination of air breathing and rocket propulsion systems and is fully reusable, with horizontal takeoff and landing capability. The orbiter is carried in an aerodynamically designed bay in the aft section of the booster vehicle to the staging altitude. This TSTO Spacecraft design meets the requirements of replacing the aging Space Shuttle system with a more easily maintained vehicle with more flexible mission capability. Author (revised)

AUTONOMOUS SPACE PROCESSOR FOR ORBITAL DEBRIS (ASPOD)

Kumar Ramohalli, Dominique Mitchell, and Brett Taft 1992 330 p
(Contract NASw-4435)
(NASA-CR-195521; NAS 1.26:195521) Avail: CASI HC A15/MF A03

A project in the Advanced Design Program at the University of Arizona is described. The project is named the Autonomous Space Processor for Orbital Debris (ASPOD) and is a Universities Space Research Association (USRA) sponsored design project. The development of ASPOD and the students' abilities in designing and building a prototype spacecraft are the ultimate goals of this project. This year's focus entailed the development of a secondary robotic arm and end-effector to work in tandem with an existent arm in the removal of orbital debris. The new arm features the introduction of composite materials and a linear drive system, thus producing a light-weight and more accurate prototype. The main characteristic of the end-effector design is that it incorporates all of the motors and gearing internally, thus not subjecting them to the harsh space environment. Furthermore, the arm and the end-effector are automated by a control system with positional feedback. This system is composed of magnetic and optical encoders connected to a 486 PC via two servo-motor controller cards. Programming a series of basic routines and sub-routines allowed the ASPOD prototype to become more autonomous. The new system is

expected to perform specified tasks with a positional accuracy of 0.5 cm.

ORBITAL DOCKING SYSTEM CENTERLINE COLOR TELEVISION CAMERA SYSTEM TEST
Philip T. Mongan Dec. 1993 25 p
(NASA-TM-104783; S-743; NAS 1.15:104783) Avail: CASI HC A03/MF A01

A series of tests was run to verify that the design of the centerline color television camera (CTVC) system is adequate optically for the STS-71 Space Shuttle Orbiter docking mission with the Mir space station. In each test, a mockup of the Mir consisting of hatch, docking mechanism, and docking target was positioned above the Johnson Space Center's full fuselage trainer, which simulated the Orbiter with a mockup of the external airlock and docking adapter. Test subjects viewed the docking target through the CTVC under 30 different lighting conditions and evaluated target resolution, field of view, light levels, light placement, and methods of target alignment. Test results indicate that the proposed design will provide adequate visibility through the centerline camera for a successful docking, even with a reasonable number of light failures. It is recommended that the flight deck crew have individual switching capability for docking lights to provide maximum shadow management and that centerline lights be retained to deal with light failures and user preferences. Procedures for light management should be developed and target alignment aids should be selected during simulated docking runs. Author

A SMALL SATELLITE DESIGN FOR DEEP SPACE NETWORK TESTING AND TRAINING Final Design Report
Dennis McWilliams, Clint Slatton, Cassidy Norman, Joe Araiza, Jason Jones, Mark Tedesco, Michael Wortman, John Opiela, Pat Lett, and Michael Clavenna 8 May 1993 114 p Original contains color illustrations
(Contract NASw-4435)
(NASA-CR-195526; NAS 1.26:195526) Avail: CASI HC A06/MF A02; 2 functional color pages

With the continuing exploration of the Solar System and the reemphasis on Earth focused missions, the need for faster data transmission rates has grown. Ka-band could allow a higher data delivery rate over the current X-band, however the adverse effects of the Earth's atmosphere on Ka are as yet unknown. The Deep Space Network and Jet Propulsion Lab have proposed to launch a small satellite that would simultaneously transmit X and Ka signals to test the viability of switching to Ka-band. The Mockingbird Design Team at the University of Texas at Austin applied small satellite design principles to achieve this objective. The Mockingbird design, named BATSAT, incorporates simple, low-cost systems designed for university production and testing. The BATSAT satellite is a 0.64 m diameter, spherical panel led satellite, mounted with solar cells and omni-directional antennae. The antennae configuration negates the need for active attitude control or spin stabilization. The space-frame truss structure was designed for 11 g launch loads while allowing for easy construction and solar-panel mounting. The communication system transmits at 1 mW by carrying the required Ka and X-band transmitters, as well as an S band transmitter used for DSN training. The power system provides the 8.6 W maximum power requirements via silicon solar arrays and nickel-cadmium batteries. The BATSAT satellite will be lofted into an 1163 km, 70 deg orbit by the Pegasus launch system. This orbit fulfills DSN dish slew rate requirements while keeping the satellite out of the heaviest regions of the Van Allen radiation belts. Each of the three DSN stations capable of receiving Ka-band (Goldstone, Canberra, and Madrid) will have an average of 85 minutes of view-time per day over the satellites ten year design life. Mockingbird Designs hopes that its small satellite design will not only be applicable to this specific mission scenario, but that it could easily be modified for instrument capability for university, government, and/or commercial research. HUBBLE SPACE TELESCOPE HIGH SPEED PHOTOMETER SCIENCE VERIFICATION TEST REPORT
Evan E. Richards Jul. 1992 157 p
(Contract NAS5-24487)
(NASA-CR-189322; NAS 1.26:189322) Avail: CASI HC A08/MF A02

The purpose of this report is to summarize the results of the HSP Science Verification (SV) tests, the status of the HSP at the end of the SV period, and the work remaining to be done. The HSP OV report (November 1991) covered all activities (OV, SV, and SAO) from launch to the completion of phase three alignment, OV 3233 performed in the 91154 SMS, on June 8, 1991. This report covers subsequent activities through May 1992. Author (revised)

SATELLITE SITUATION REPORT, VOLUME 33, NUMBER 4
31 Dec. 1993 403 p See N94-15712, vol. 33, no. 3
(NASA-TM-109677; NAS 1.15:109677) Avail: CASI HC A18/MF A04

The Satellite Situation Report is a listing of those satellites (objects) currently in orbit and those which have previously orbited the Earth. Some objects are too small or too far from the Earth's surface to be detected; therefore, the Satellite Situation Report does not include all manmade objects orbiting the Earth. Generally, satellites are classified as follows: (1) Payloads may contain one or more functioning or nonfunctioning experiments. Usually only the owners of the satellites know if the experiments are functioning, and there is no one source which indicates the operational status of all payloads and/or experiments. Payloads are normally the first listed in the Satellite Situation Report, i.e., 1982 087A, unless there are multiple payloads for the launch. In which case, the first objects cataloged are usually all payloads, unless a subsequent payload is later identified after objects other than payloads have been cataloged. (2) Platforms are used to support a payload while it is being placed into orbit. A platform may remain in orbit long after its purpose is served, usually longer than rocket bodies. It is usually the first object identified in the Satellite Situation Report listing after the payload(s), i.e., 1982 087B (when a platform is not used, the first object after the payload(s) is usually the rocket body). (3) Rocket bodies are used to place the payload and platform (if one is used) into orbit. Some launches may have more than one rocket body because of the payload weight or the type of orbit or experiment. Most rocket bodies decay within a short time after the payload (and platform) have achieved orbit. Rocket bodies are usually the third object listed in the Satellite Situation Report after the payload(s), i.e., 1982 087C. (4) Debris in orbit occurs when parts (nose cone shrouds, lens or hatch covers) are separated from the payload, when rocket bodies or payloads disintegrate or explode, or when objects are placed into free space from manned orbiting spacecraft during operations. Debris is detected by its size and distance from the Earth. Debris objects are the last objects after payload(s), platform, and rocket body(s) listed in the Satellite Situation Report, i.e., 1982 087D, 1982 087E, 1982 087F. Author (revised)

THERMAL CONTROL SYSTEM FOR SPACE STATION FREEDOM PHOTOVOLTAIC POWER MODULE
Thomas H. Hacha and Laura Howard (Rockwell International Corp., Canoga Park, CA.) Jan. 1994 13 p Presented at the 22nd International Conference on Environmental Systems, Seattle, WA, 13-16 Jul. 1992; sponsored by SAE See also A93-41305
(RTOP 474-46-10)
(NASA-TM-105650; E-7014; NAS 1.15:105650) Avail: CASI HC A03/MF A01

The electric power for Space Station Freedom (SSF) is generated by the solar arrays of the photovoltaic power modules (PVM's) and conditioned, controlled, and distributed by a power management and distribution system. The PVM's are located outboard of the alpha gimbals of SSF. A single-phase thermal control system is being developed to provide thermal control of PVM electrical equipment and energy storage batteries. This system uses ammonia as the coolant and a direct-flow deployable radiator. The description and development status of the PVM thermal control system is presented.

DESIGN OF ORBITAL DEBRIS SHIELDS FOR OBLIQUE HYPERVELOCITY IMPACT Final Report

Eric P. Fahrenthold 14 Feb. 1994 111 p
(Grant NAG9-586)
(NASA-CR-195152; NAS 1.26:195152) Avail: CASI HC A06/MF A02

A new impact debris propagation code was written to link CTH simulations of space debris shield perforation to the Lagrangian finite element code DYNA3D, for space structure wall impact simulations. This software (DC3D) simulates debris cloud evolution using a nonlinear elastic-plastic deformable particle dynamics model, and renders computationally tractable the supercomputer simulation of oblique impacts on Whipple shield protected structures. Comparison of three dimensional, oblique impact simulations with experimental data shows good agreement over a range of velocities of interest in the design of orbital debris shielding. Source code developed during this research is provided on the enclosed floppy disk. An abstract based on the work described was submitted to the 1994 Hypervelocity Impact Symposium. Author (revised)

IOWA SATELLITE PROJECT ISAT-1
25 Jul. 1993 298 p
(Contract NASw-4435)
(NASA-CR-195517; NAS 1.26:195517) Avail: CASI HC A13/MF A03

Satellite systems to date have been mainly scientific in nature. Only a few systems have been of direct use to the public such as for telephone or television transmission. Space enterprises have remained a mystery to the general public and beyond the reach of the small business community. The result is a less than supportive public when it comes to space activities. The purpose of the ISAT-1 program is to develop a small and relatively inexpensive satellite that will serve the State of Iowa, primarily for educational purposes. It will provide products, services, and activities that will be educational, practical, and useful for a large number for people. The emphasis is on public awareness, 'space literacy', and routine practical applications rather than high technology. The initial conceptual design phase was complete when the current team took over the project. Some areas of the conceptual design were taken a little farther, but for the most part this team started at the detailed design stage. Derived from text

EXTENDED DURATION LUNAR LANDER
Nikola Babic, Matt Carter, Donna Cosper, David Garza, Eloy Gonzalez, David Goodine, Edward Hirst, Ray Li, Martin Lindsey, and Tony Ng 15 May 1993 116 p Original contains color illustrations
(Contract NASw-4435)
(NASA-CR-195527; NAS 1.26:195527) Avail: CASI HC A06/MF A02; 2 functional color pages

Selenium Technologies has been conducting preliminary design work on a manned lunar lander for use in NASA's First Lunar Outpost (FLO) program. The resulting lander is designed to carry a crew of four astronauts to a prepositioned habitat on the lunar surface, remain on the lunar surface for up to 45 days while the crew is living in the habitat, then return the crew to earth via direct reentry and land recovery. Should the need arise, the crew can manually guide the lander to a safe lunar landing site, and live in the lander for up to ten days on the surface. Also, an abort to earth is available during any segment of the mission. The main propulsion system consists of a cluster of four modified Pratt and Whitney RL10 rocket engines that use liquid methane (LCH4) and liquid oxygen (LOX). Four engines are used to provide redundancy and a satisfactory engine out capability. Differences between the new propulsion system and the original system include slightly smaller engine size and lower thrust per engine, although specific impulse remains the same despite the smaller size. Concerns over nozzle ground clearance and engine reliability, as well as more information from Pratt and Whitney, brought about this change. The power system consists of a combination of regenerative fuel cells and solar arrays. While the lander is in flight to or from the moon, or during the lunar night, fuel cells provide all electrical power. During the lunar day, solar arrays are deployed to provide electrical power for the lander as well as electrolyzers, which separate some water back into hydrogen and oxygen for later use by the fuel cells. Total storage requirements for oxygen, hydrogen, and water are 61 kg, 551 kg, and 360 kg, respectively. The lander is a stage-and-a-half design with descent propellant, cargo, and landing gear contained in the descent stage, and the main propulsion system, ascent propellant, and crew module contained in the ascent stage. The primary structure for both stages is a truss, to which all tanks and components are attached. The crew module is a conical shape similar to that of the Apollo Command Module, but significantly larger with a height and maximum diameter of six meters. Author (revised)

PRELIMINARY DESIGN OF A UNIVERSAL MARTIAN LANDER
Timothy L. Norman, David E. Gaskin, Sean Adkins, Mary Gunawan, Raquel Johnson, David MacDonnell, Andrew Parlock, John Sarick, Charles Bodwell, and Kouichi Hashimoto et al 1993 147 p
(Contract NASw-4435)
(NASA-CR-195529; NAS 1.26:195529) Avail: CASI HC A07/MF A02

In the next 25 years, mankind will be undertaking yet another giant leap forward in the exploration of the solar system: a manned mission to Mars. This journey will provide important information on the composition and history of both Mars and the Solar System. A manned mission will also provide the opportunity to study how humans can adapt to long term space flight conditions and the Martian environment. As part of the NASA/USRA program, nineteen West Virginia University students conducted a preliminary design of a manned Universal Martian Lander (UML). The UML's design will provide a 'universal' platform, consisting of four modules for living and laboratory experiments and a liquid-fuel propelled Manned Ascent Return Vehicle (MARV). The distinguishing feature of the UML is the 'universal' design of the modules which can be connected to form a network of laboratories and living quarters for future missions thereby reducing development and production costs. The WVU design considers descent to Mars from polar orbit, a six month surface stay, and ascent for rendezvous. The design begins with an unmanned UML landing at Elysium Mons followed by the manned UML landing nearby. During the six month surface stay, the eight modules will be assembled to form a Martian base where scientific experiments will be performed. The mission will also incorporate hydroponic plant growth into a Controlled Ecological Life Support System (CELSS) for water recycling, food production, and to counteract psychological effects of living on Mars. In situ fuel production for the MARV will be produced from gases in the Martian atmosphere. Following surface operations, the eight member crew will use the MARV to return to the Martian Transfer Vehicle (MTV) for the journey home to Earth. Author

MODELING OF A LARGE UNDAMPED SPACE STRUCTURE USING TIME DOMAIN TECHNIQUES M.S. Thesis
Anthony R. Nash Dec. 1993 118 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273828; AFIT/GA/ENY/93D-7) Avail: CASI HC A06

The first phase of this project was the selection of accurate time domain state space modeling techniques by comparing the models generated by various methods against a known system. The techniques selected were the Eigensystem Realization Algorithm and the Backward Least Squares method. These modeling techniques were applied to the vibration data from the PACOSS dynamic test article. The resulting model transfer function was then compared to the frequency response function of the actual system, and was found to be an accurate match for the system poles, but not for the system zeros. STEADY MOTIONS OF RIGID BODY SATELLITES IN A CENTRAL GRAVITATIONAL FIELD M.S. Thesis
Cynthia A. Provost Dec. 1993 89 p
(AD-A273742; AFIT/GA/ENY/93D-8) Avail: CASI HC A05/MF A01

Numerous studies have been conducted on equilibrium orientations of objects moving under the influence of a central gravitational field. The results of many of these studies conclude that equilibrium conditions exist only when one of the principal axes coincides with the radius vector. Furthermore, these results assume that the center of force is located within the orbit plane, thereby tracing a great circle orbit. While these previous works have approximated the gravitational potential, this study examines relative equilibria obtained by retaining an exact expression for the potential of a spherical primary body, as shown in a recent paper by Wang, Maddocks, and Krishnaprasad. The exact dynamic equations for the motion of a finite rigid body in an inverse square gravitational force field are investigated. Only circular orbits for a specific satellite model consisting of six masses connected by three massless rigid rods are considered. The system dynamics are comprised of seven nonlinear equations, which were numerically solved on a Cray computer. The existence of equilibrium orientations which establish non-great circle orbits was verified and other interesting results were noted. The operational significance of these results was also examined. DTIC

The purpose is to describe at a high level the common interface provisions and constraints placed on the NOAA-2000 instruments and the interfacing spacecraft elements in the following areas: electrical interface, mechanical interface, thermal interface, magnetic interface, electromagnetic compatibility, structural/mechanical environmental interface, contamination control, and the ionizing radiation environment. The requirements reflect the fact that these instruments must be compatible with a number of different polar orbiting satellite vehicles including the NOAA-OPQ satellites and the EUMETSAT METOP satellites. PULSAUR II is a sounding rocket experiment to investigate the pulsating aurora and related phenomena. The payload consists of a complementary set of instruments designed specifically to look at the pulsating aurora. The project will be managed by the Norwegian Space Center, with integration in Norway. The rocket is due for launch in January 1994 from the Andoya rocket range. Southwest Research Institute provided an electron sensor for this campaign. It is a 'top hat' electron spectrometer, referred to as AREA (Angle Resolving Energy Analyzer), and is based on the electron sensor developed for the CENTAUR mission. Author (revised)

HIGH ENERGY COLLIMATING FINE GRIDS FOR HESP PROGRAM Final Report
Carol D. Eberhard and Edward Frazier Dec. 1993 36 p
(Contract NAS5-32529)
(NASA-CR-189317; NAS 1.26:189317) Avail: CASI HC A03/MF A01

There is a need to develop fine pitch x-ray collimator grids as an enabling technology for planned future missions. The grids consist of an array of thin parallel strips of x-ray absorbing material, such as tungsten, with pitches ranging from 34 microns to 2.036 millimeters. The grids are the key components of a new class of spaceborne instruments known as 'x-ray modulation collimators.' These instruments are the first to produce images of celestial sources in the hard x-ray and gamma-ray spectral regions. Author (revised)

Degobah Satellite Systems (DSS), in cooperation with the University Space Research Association (USRA), NASA - Johnson Space Center (JSC), and the University of Texas, has completed the preliminary design of a satellite system to provide inexpensive on-demand video images of all or any portion of Space Station Freedom (SSF). DSS has narrowed the scope of the project to complement the work done by Mr. Dennis Wells at Johnson Space Center. This three month project has resulted in completion of the preliminary design of AERCAM, the Autonomous Extravehicular Robotic Camera, detailed in this design report. This report begins by providing information on the project background, describing the mission objectives, constraints, and assumptions. Preliminary designs for the primary concept and satellite subsystems are then discussed in detail. Included in the technical portion of the report are detailed descriptions of an advanced imaging system and docking and safing systems that ensure compatibility with the SSF. The report concludes by describing management procedures and project costs. Derived from text

(Contract W-7405-eng-48)
(DE94-001533; UCRL-JC-114643; CONF-930948-1) Avail: CASI HC A02

A plasma thruster operating at high specific impulse (greater than or equal to 3500 s) has been proposed to be based on electron-cyclotron resonance heating of whistler waves propagating on a plasma column on a magnetic hill. Calculations using a particle-in-cell code demonstrate that the distortion of the electron velocity distribution by the heating significantly reduces the flow of plasma up the field, greatly improving efficiency and reducing material interactions relative to a thermal plasma. These and other calculations are presented together with initial experiments on the plasma generated in the proposed device. The experiments are conducted in a magnetic field (3.3 x 10(exp -2) T at resonance) and a magnetic mirror ratio of 5. Microwaves (0.915 GHz, less than 20 kW) are coupled to the plasma with a helical antenna. Vacuum field measurements are in good agreement with prediction. The desired plasma spatial distribution has not yet been achieved. DOE

On 8-9 Sep. 1993, the Propulsion Engineering Research Center (PERC) at The Pennsylvania State University held its Fifth Annual Symposium. PERC was initiated in 1988 by a grant from the NASA Office of Aeronautics and Space Technology as a part of the University Space Engineering Research Center (USERC) program; the purpose of the USERC program is to replenish and enhance the capabilities of our Nation's engineering community to meet its future space technology needs. The Centers are designed to advance the state-of-the-art in key space-related engineering disciplines and to promote and support engineering education for the next generation of engineers for the national space program and related commercial space endeavors. Research on the following areas was initiated: liquid, solid, and hybrid chemical propulsion, nuclear propulsion, electrical propulsion, and advanced propulsion concepts. For individual titles, see N94-23029 through N94-23071.

MEASUREMENT OF INTACT-CORE LENGTH OF ATOMIZING LIQUID JETS BY IMAGE DECONVOLUTION c34

Roger Woodward, Robert Burch, Kenneth Kuo, and Fan-Bill Cheung *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 1-4 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

The investigation of liquid jet breakup and spray development is critical to the understanding of combustion phenomena in liquid propellant rocket engines. Much work has been done to characterize low-speed liquid jet breakup and dilute sprays, but atomizing jets and dense sprays have yielded few quantitative measurements due to their high liquid load fractions and hence their optical opacity. Focus was on a characteristic of the primary breakup process of round liquid jets, namely the length of the intact-liquid core. The specific application considered is that of shear-coaxial-type rocket engine injectors in which liquid oxygen is injected through the center post while high velocity gaseous hydrogen is injected through a concentric annulus, providing a shear force to the liquid jet surface. Real-time x ray radiography, capable of imaging through the dense two-phase region surrounding the liquid core, is used to make the measurements. The intact-liquid-core length data were obtained and interpreted using two conceptually different methods to illustrate the effects of chamber pressure, gas-to-liquid momentum ratio, and cavitation. SMALL ROCKET FLOWFIELD DIAGNOSTIC CHAMBERS

Sybil Morren and Brian Reed *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 5-11 (For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

Instrumented and optically-accessible rocket chambers are being developed to be used for diagnostics of small rocket (less than 440 N thrust level) flowfields. These chambers are being tested to gather local fluid dynamic and thermodynamic flowfield data over a range of test conditions. This flowfield database is being used to better understand mixing and heat transfer phenomena in small rockets, influence the numerical modeling of small rocket flowfields, and characterize small rocket components. The diagnostic chamber designs include: a chamber design for gathering wall temperature profiles to be used as boundary conditions in a finite element heat flux model; a chamber design for gathering inner wall temperature and static pressure profiles; and optically-accessible chamber designs, to be used with a suite of laser-based diagnostics for gathering local species concentration, temperature, density, and velocity profiles. These chambers were run with gaseous hydrogen/gaseous oxygen (GH_2/GO_2) propellants, while subsequent versions will be run on liquid oxygen/hydrocarbon (LOX/HC) propellants. The purpose, design, and initial test results of these small rocket flowfield diagnostic chambers are summarized. Author (revised)

A THEORETICAL EVALUATION OF ALUMINUM GEL PROPELLANT TWO-PHASE FLOW LOSSES ON VEHICLE PERFORMANCE

Donn C. Mueller and Stephen R. Turns *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 12-16 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

A one-dimensional model of a hydrocarbon/Al/O_2(gaseous) fueled rocket combustion chamber was developed to study secondary atomization effects on propellant combustion. This chamber model was coupled with a two dimensional, two-phase flow nozzle code to estimate the two-phase flow losses associated with solid combustion products. Results indicate that moderate secondary atomization significantly reduces propellant burnout distance and Al_2O_3 particle size; however, secondary atomization provides only moderate decreases in two-phase flow induced I(sub sp) losses. Despite these two-phase flow losses, a simple mission study indicates that aluminum gel propellants may permit a greater maximum payload than the hydrocarbon/O_2 bi-propellant combination for a vehicle of fixed propellant volume. Secondary atomization was also found to reduce radiation losses from the solid combustion products to the chamber walls, primarily through reductions in propellant burnout distance. Author (revised)

LASER DIAGNOSTICS FOR SMALL ROCKETS

Frank J. Zupanc and Wilhelmus A. deGroot (Sverdrup Technology, Inc., Cleveland, OH.) *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 17-22 (For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

Two nonintrusive flowfield diagnostics based on spectrally-resolved elastic (Rayleigh) and inelastic (Raman) laser light scattering were developed for obtaining local flowfield measurements in low-thrust gaseous H_2/O_2 rocket engines. The objective is to provide an improved understanding of phenomena occurring in small chemical rockets in order to facilitate the development and validation of advanced computational fluid dynamics (CFD) models for analyzing engine performance. The laser Raman scattering diagnostic was developed to measure major polyatomic species number densities and rotational temperatures in the high-density flowfield region extending from the injector through the chamber throat. Initial application of the Raman scattering diagnostic provided O_2 number density and rotational temperature measurements in the exit plane of a low area-ratio nozzle and in the combustion chamber of a two-dimensional, optically-accessible rocket engine. In the low-density nozzle exit plane region where the Raman signal is too weak, a Doppler-resolved laser Rayleigh scattering diagnostic was developed to obtain axial and radial mean gas velocities, and in certain cases, H_2O translational temperature and number density. The results from these measurements were compared with theoretical predictions from the RPLUS CFD code for analyzing rocket engine performance. Initial conclusions indicate that a detailed and rigorous modeling of the injector is required in order to make direct comparisons between laser diagnostic measurements and CFD predictions at the local level. Author (revised)

CFD ANALYSES OF COMBUSTOR AND NOZZLE FLOWFIELDS

Hsin-Hua Tsuei and Charles L. Merkle *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 23-27 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

The objectives of the research are to improve design capabilities for low thrust rocket engines through understanding of the detailed mixing and combustion processes. A Computational Fluid Dynamic (CFD) technique is employed to model the flowfields within the combustor, nozzle, and near plume field. The computational modeling of the rocket engine flowfields requires the application of the complete Navier-Stokes equations, coupled with species diffusion equations. Of particular interest is a small gaseous hydrogen-oxygen thruster which is considered as a coordinated part of an ongoing experimental program at NASA LeRC. The numerical procedure is performed on both time-marching and time-accurate algorithms, using an LU approximate factorization in time, flux split upwinding differencing in space. The integrity of fuel film cooling along the wall, its effectiveness in the mixing with the core flow including unsteady large scale effects, the resultant impact on performance and the assessment of the near plume

flow expansion to finite pressure altitude chamber are addressed.

LOX DROPLET VAPORIZATION IN A SUPERCRITICAL FORCED CONVECTIVE ENVIRONMENT **c34**
Chia-Chun Hsiao and Vigor Yang *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 28-32 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Modern liquid rocket engines often use liquid oxygen (LOX) and liquid hydrogen (LH2) as propellants to achieve high performance, with the engine operational conditions in the supercritical regimes of the propellants. Once the propellant exceeds its critical state, it essentially becomes a puff of dense fluid. The entire field becomes a continuous medium, and no distinct interfacial boundary between the liquid and gas exists. Although several studies have been undertaken to investigate the supercritical droplet behavior at quiescent conditions, very little effort has been made to address the fundamental mechanisms associated with LOX droplet vaporization in a supercritical, forced convective environment. The purpose is to establish a theoretical framework within which supercritical droplet dynamics and vaporization can be studied systematically by means of an efficient and robust numerical algorithm. EVAPORATION AND COMBUSTION OF LOX UNDER SUPERCRITICAL AND SUBCRITICAL CONDITIONS **c25**
A. S. Yang, W. H. Hsieh, and K. K. Kuo *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 33-38 (For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

The objective is to study the evaporation and combustion of LOX under supercritical and subcritical conditions both experimentally and theoretically. In the evaporation studies, evaporation rate and surface temperature were measured when LOX vaporizing in helium environments at pressures ranging from 5 to 68 atm. A Varian 3700 gas chromatograph was employed to measure the oxygen concentration above the LOX surface. For the combustion tests, high-magnification video photography was used to record direct images of the flame shape of a LOX/H2/He laminar diffusion flame. The gas composition in the post-flame region is also being measured with the gas sampling and chromatography analysis. These data are being used to validate the theoretical model. A comprehensive theoretical model with the consideration of the solubility of ambient gases as well as variable thermophysical properties was formulated and solved numerically to study the gasification and burning of LOX at elevated pressures. The calculated flame shape agreed reasonably well with the edge of the observed luminous flame surface. The effect of gravity on the flame structure of laminar diffusion flames was found to be significant. In addition, the predicted results using the flame-sheet model were compared with those based upon full equilibrium calculations (which considered the formation of intermediate species) at supercritical pressures. Except at the flame front where temperature exceeded 2,800 K, the flame-sheet and equilibrium solutions in terms of temperature distributions were in very close agreement. The temperature deviation in the neighborhood of the flame front is caused by the effect of high-temperature dissociation. Author (revised)

SMALL ROCKET RESEARCH AND TECHNOLOGY
Steven Schneider and James Biaglow *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 50-53 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Small chemical rockets are used on nearly all space missions. The small rocket program provides propulsion technology for civil and government space systems. Small rocket concepts are developed for systems which encompass reaction control for launch and orbit transfer systems, as well as on-board propulsion for large space systems and earth orbit and planetary spacecraft. Major roles for on-board propulsion include apogee kick, delta-V, de-orbit, drag makeup, final insertions, north-south stationkeeping, orbit change/trim, perigee kick, and reboost. The program encompasses efforts on earth-storable, space storable, and cryogenic propellants. The earth-storable propellants include nitrogen tetroxide (NTO) as an oxidizer with monomethylhydrazine (MMH) or anhydrous hydrazine (AH) as fuels. The space storable propellants include liquid oxygen (LOX) as an oxidizer with hydrazine or hydrocarbons such as liquid methane, ethane, and ethanol as fuels. Cryogenic propellants are LOX or gaseous oxygen (GOX) as oxidizers and liquid or gaseous hydrogen as fuels. Improved performance and lifetime for small chemical rockets are sought through the development of new predictive tools to understand the combustion and flow physics, the introduction of high temperature materials to eliminate fuel film cooling and its associated combustion inefficiency, and improved component designs to optimize performance. Improved predictive technology is sought through the comparison of both local and global predictions with experimental data. Results indicate that modeling of the injector and combustion process in small rockets needs improvement. High temperature materials require the development of fabrication processes, a durability data base in both laboratory and rocket environments, and basic engineering property data such as strength, creep, fatigue, and work hardening properties at both room and elevated temperature. Promising materials under development include iridium-coated rhenium and a ceramic composite of mixed hafnium carbide and tantalum carbide reinforced with graphite fibers.

The performance and stability of liquid rocket engines is determined to a large degree by atomization, mixing, and combustion processes. Control over these processes is exerted through the design of the injector. Injectors in liquid rocket engines are called upon to perform many functions. They must first of all mix the propellants to provide suitable performance in the shortest possible length. For main injectors, this is driven by the tradeoff between the combustion chamber performance, stability, efficiency, and its weight and cost. In gas generators and preburners, however, it is also driven by the possibility of damage to downstream components, for example piping and turbine blades. This can occur if unburned fuel and oxidant later react to create hot spots. Weight and cost considerations require that the injector design be simple and lightweight. For reusable engines, the injectors must also be durable and easily maintained. Suitable atomization and mixing must be produced with as small a pressure drop as possible, so that the size and weight of pressure vessels and turbomachinery can be minimized. However, the pressure drop must not be so small as to promote feed system coupled instabilities. Another important function of the injectors is to ensure that the injector face plate and the chamber and nozzle walls are not damaged. Typically this requires reducing the heat transfer to an acceptable level and also keeping unburned oxygen from chemically attacking the walls, particularly in reusable engines. Therefore the mixing distribution is often tailored to be fuel-rich near the walls. Wall heat transfer can become catastrophically damaging in the presence of acoustic instabilities, so the injector must prevent these from occurring at all costs. In addition to acoustic stability (but coupled with it), injectors must also be kinetically stable. That is, the flame itself must maintain ignition in the combustion chamber. This is not typically a problem with main injectors, but can be a consideration in preburners, where the desire to keep turbine inlet temperatures as cool as possible can make it advantageous for the preburners to operate as far from stoichiometry as can be tolerated. For some missions such as single stage to orbit, all of the above requirements must be maintained over a throttleable range, for example 5:1 to 10:1. Finally, the injectors must be ignitable during startup where pressures and temperatures are far from design conditions, and ignition transients must be minimized in order to avoid damage to engine components. In order to satisfy these various constraints, the injector designer must be able to perform design tradeoff studies, and it is important that this be done with minimal time and costs. In fact, it can easily be argued that reducing engine development time and costs is essential to maintaining U.S. competitiveness in space. The Propulsion Directorate of the Phillips Laboratory has invested in a number of programs to advance liquid rocket engine technology, and several of these are directed at improving design tools for liquid rocket injectors. The purpose of the presentation will be to describe some of these latter programs.

AN EXPERIMENTAL STUDY OF CHARACTERISTIC COMBUSTION-DRIVEN FLOWS FOR CFD VALIDATION

S. Pal, J. J. Merenich, M. D. Moser, and R. J. Santoro *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 58-63
(For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

The application of laser-based diagnostic techniques has become commonplace to a wide variety of combustion problems. New insights into combustion phenomena at a level previously unattainable has been made possible by non-intrusive measurements of velocity, temperature, and species. However, due to the adverse conditions which exist inside rocket engines, relatively few studies have addressed these combustion environments. The high pressure, high speed, combusting environment in a rocket engine prohibits the application of several measurement techniques. However, in the rocket community, there is a critical need for rocket flow field data to validate computational fluid dynamic (CFD) codes. Currently at Penn State, there is an effort to obtain flowfield measurements inside a rocket engine. Velocity measurements have been made inside the combustion chamber of a uni-element (shear coaxial injector) optically accessible rocket chamber at several axial locations downstream of the injector. These measurements, combined with future measurements, will provide benchmark data for CFD code validation. Author (revised)

NUMERICAL PARAMETRIC STUDIES OF SPRAY COMBUSTION INSTABILITY **c25**

M. Z. Pindera *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 64-68 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

A coupled numerical algorithm has been developed for studies of combustion instabilities in spray-driven liquid rocket engines. The model couples gas and liquid phase physics using the method of fractional steps. Also introduced is a novel, efficient methodology for accounting for spray formation through direct solution of liquid phase equations. Preliminary parametric studies show marked sensitivity of spray penetration and geometry to droplet diameter, considerations of liquid core, and acoustic interactions. Less sensitivity was shown to the combustion model type although more rigorous (multi-step) formulations may be needed for the differences to become apparent. Derived from text

SPRAY FORMATION PROCESSES OF IMPINGING JET INJECTORS **c34**

W. E. Anderson, H. M. Ryan, S. Pal, and R. J. Santoro *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 69-74
(For primary document see N94-23028 06-20)
(Grant AF-AFOSR-0336-91)
Avail: CASI HC A02/MF A03

A study examining impinging liquid jets has been underway to determine physical mechanisms responsible for combustion instabilities in liquid bi-propellant rocket engines. Primary atomization has been identified as an important process. Measurements of atomization length, wave structure, and drop size and velocity distribution were made under various ambient conditions. Test parameters included geometric effects and flow effects. It was observed that pre-impingement jet conditions, specifically whether they were laminar or turbulent, had the major effect on primary atomization. Comparison of the measurements with results from a two dimensional linear aerodynamic stability model of a thinning, viscous sheet were made. Measured turbulent impinging jet characteristics were contrary to model predictions; the structure of waves generated near the point of jet impingement were dependent primarily on jet diameter and independent of jet velocity. It has been postulated that these impact waves are related to pressure and momentum fluctuations near the impingement region and control the eventual disintegration of the liquid sheet into ligaments. Examination of the temporal characteristics of primary atomization (ligament shedding frequency) strongly suggests that the periodic nature of primary atomization is a key process in combustion instability. INHERENT STABILITY OF CENTRAL ELEMENT COAXIAL LIQUID-LIQUID INJECTORS **c34**

Frank J. Stoddard *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 75-76 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Most TRW liquid bi-propellant rocket engines built over the past thirty-plus years have employed a central element coaxial pintle injector and have operated with liquid/liquid propellant injection. This injector is a patented design exclusive to TRW and has unique features that make the rocket engine combustion characteristics different from those of other types of injector engine designs. Its many benefits include excellent combustion performance, efficient deep throttling, adaptability to low cost manufacturing, and high reliability. Approximately 200 pintle injector engines of various sizes and operating on a variety of propellants have been flown without a single inflight failure. An especially important feature of the pintle injector engine is its apparent inherent combustion stability. In over thirty years of development, testing, and production, TRW has never experienced combustion instability in any of its pintle injector engine designs. This has been true of engines operating over a range of thrust from 5 to 250,000 lbs. on earth-storable hypergolic propellants and a large number of smaller engines operating on a variety of propellants (21 combinations) in long duration-firing, pulsing (down to 2 msec), and deep throttling (as much as 19:1) modes. Operating chamber pressures have ranged from 10 to 3,500 psia. This record is particularly impressive given that typical TRW design practice does not consider combustion instability as an issue and no pintle engine has ever employed stability-enhancing features, such as baffles or acoustically resonant chambers. In spite of this, TRW engines have operated stably in regimes not possible with other types of injectors. Various physical explanations and combustion process models for this favorable stability characteristic have been postulated. However, a definitive study that unequivocally establishes the important stabilizing mechanisms still remains to be conducted. Derived from text

AXISYMMETRIC SINGLE SHEAR ELEMENT COMBUSTION INSTABILITY EXPERIMENT **c25**
Kevin J. Breisacher *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 77-81 See also N94-10763 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

The combustion stability characteristics of a combustor consisting of a single shear element and a cylindrical chamber utilizing LOX and gaseous hydrogen as propellants are presented. The combustor geometry and the resulting longitudinal mode instability are axisymmetric. Hydrogen injection temperature and pyrotechnic pulsing were used to determine stability boundaries. Mixture ratio, fuel annulus gap, and LOX post configuration were varied. Performance and stability data were obtained for chamber pressures of 300 and 1000 psia. Author

DEVELOPMENT OF A DROPLET BREAKUP MODEL CONSIDERING AERODYNAMIC AND DROPLET COLLISION EFFECTS **c34**
K. L. Wert and H. R. Jacobs *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 82-87 (For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

A model is currently under development to predict the occurrence and outcome of spray droplet breakup induced by aerodynamic forces and droplet collisions. It is speculated that these phenomena may be significant in determining the droplet size distribution in a spray subjected to acoustic velocity fluctuations. The goal is to integrate this breakup model into a larger spray model in order to examine the effects of combustion instabilities on liquid rocket motor fuel sprays. The model is composed of three fundamental components: a dynamic equation governing the deformation of the droplet, a criterion for breakage based on the amount of deformation energy stored in the droplet and an energy balance based equation to predict the Sauter mean diameter of the fragments resulting from breakup. Comparison with published data for aerodynamic breakup indicates good agreement in terms of predicting the occurrence of breakup. However, the model significantly over predicts the size of the resulting fragments. This portion of the model is still under development. Author

DEVELOPMENT OF A COMPUTATIONAL TESTBED FOR NUMERICAL SIMULATION OF COMBUSTION INSTABILITY **c25**
Jeffrey Grenda, Sankaran Venkateswaran, and Charles L. Merkle *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 88-92 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

A synergistic hierarchy of analytical and computational fluid dynamic techniques is used to analyze three-dimensional combustion instabilities in liquid rocket engines. A mixed finite difference/spectral procedure is employed to study the effects of a distributed vaporization zone on standing and spinning instability modes within the chamber. Droplet atomization and vaporization are treated by a variety of classical models found in the literature. A multi-zone, linearized analytical solution is used to validate the accuracy of the numerical simulations at small amplitudes for a distributed vaporization region. This comparison indicates excellent amplitude and phase agreement under both stable and unstable operating conditions when amplitudes are small and proper grid resolution is used. As amplitudes get larger, expected nonlinearities are observed. The effect of liquid droplet temperature fluctuations was found to be of critical importance in driving the instabilities of the combustion chamber. Author

SHEAR COAXIAL INJECTOR INSTABILITY MECHANISMS **c34**
T. Kaltz, M. Glogowski, and M. M. Micci *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 93-96 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Although stable operating regimes for cryogenic coaxial injectors have been empirically determined, there is no knowledge of the spray characteristics corresponding to stable operation, or the physical processes which produce the atomization patterns that result in stable or unstable operation. The current engineering method for determining the stable operating regime of a cryogenic coaxial injector is the 'hydrogen temperature ramping' method, however there is no definitive knowledge of whether the hydrogen temperature influences the chamber stability by decreasing the injected gas velocity, by affecting a recirculation region at the base of the LOX Post, or by changing the pressure drop across the injector, allowing chamber pressure oscillations to couple to the fuel feed system. Results for the injector response from a linearized lumped-element model are presented as a function of temperature and frequency. LDV measurements in the recess region at the base of the LOX post show reverse flow indicative of a recirculation region. Finally, Phase Doppler Particle Analyzer (PDPA) measurements of droplet size and velocity distributions are discussed for a coaxial injector element similar to the SSME preburner element operating with water and air at atmospheric pressure and liquid and gaseous nitrogen at 20 bars. NUMERICAL INVESTIGATION OF TWO- AND THREE-DIMENSIONAL HEAT TRANSFER IN EXPANDER CYCLE ENGINES
Robert L. Burch and Fan-Bill Cheung *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 97-100 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

The concept of using tube canting for enhancing the hot-side convective heat transfer in a cross-stream tubular rocket combustion chamber is evaluated using a CFD technique in this study. The heat transfer at the combustor wall is determined from the flow field generated by a modified version of the PARC Navier-Stokes Code, using the actual dimensions, fluid properties, and design parameters of a split-expander demonstrator cycle engine. The effects of artificial dissipation on convergence and solution accuracy are investigated. Heat transfer results predicted by the code are presented. The use of CFD in heat transfer calculations is critically examined to demonstrate the care needed in the use of artificial dissipation for good convergence and accurate solutions. Author

FLOW VISUALIZATION STUDY IN HIGH ASPECT RATIO COOLING CHANNELS FOR ROCKET ENGINES
Michael L. Meyer and James E. Giuliani (Ohio Aerospace Inst., Brook Park.) *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 101-105 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

The structural integrity of high pressure liquid propellant rocket engine thrust chambers is typically maintained through regenerative cooling. The coolant flows through passages formed either by constructing the chamber liner from tubes or by milling channels in a solid liner. Recently, Carlile and Quentmeyer showed life extending advantages (by lowering hot gas wall temperatures) of milling channels with larger height to width aspect ratios (AR is greater than 4) than the traditional, approximately square cross section, passages. Further, the total coolant pressure drop in the thrust chamber could also be reduced, resulting in lower turbomachinery power requirements. High aspect ratio cooling channels could offer many benefits to designers developing new high performance engines, such as the European Vulcain engine (which uses an aspect ratio up to 9). With platelet manufacturing technology, channel aspect ratios up to 15 could be formed offering potentially greater benefits. Some issues still exist with the high aspect ratio coolant channels. In a coolant passage of circular or square cross section, strong secondary vortices develop as the fluid passes through the curved throat region. These vortices mix the fluid and bring lower temperature coolant to the hot wall. Typically, the circulation enhances the heat transfer at the hot gas wall by about 40 percent over a straight channel. The effect that increasing channel aspect ratio has on the curvature heat transfer enhancement has not been sufficiently studied. If the increase in aspect ratio degrades the secondary flow, the fluid mixing will be reduced. Analysis has shown that reduced coolant mixing will result in significantly higher wall temperatures, due to thermal stratification in the coolant, thus decreasing the benefits of the high aspect ratio geometry. A better understanding of the fundamental flow phenomena in high aspect ratio channels with curvature is needed to fully evaluate the benefits of this geometry. The fluid dynamic and conjugate heat transfer problem of high aspect ratio rocket engine coolant channels are being investigated numerically, but these efforts have been hampered by a lack of validating data. Wall temperature data is available for the conjugate problem for channels without curvature and aspect ratio = 5.0, and unheated fluid dynamic data are available for square and circular cross section channels with curvature at Reynold's numbers up to 40,000. But the effects of aspect ratio on secondary flow development have not been experimentally studied. To provide some insight into the effects of channel aspect ratio on secondary flow and to qualitatively provide anchoring for the numerical codes, a flow visualization experiment was initiated at the NASA Lewis Research Center. CFD ANALYSES OF COOLANT CHANNEL FLOWFIELDS

Jennifer A. Yagley, Jinzhang Feng, and Charles L. Merkle *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 106-110 See also A93-49715 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

The flowfield characteristics in rocket engine coolant channels are analyzed by means of a numerical model. The channels are characterized by large length to diameter ratios, high Reynolds numbers, and asymmetrical heating. At representative flow conditions, the channel length is approximately twice the hydraulic entrance length so that fully developed conditions would be reached for a constant property fluid. For the supercritical hydrogen that is used as the coolant, the strong property variations create significant secondary flows in the cross-plane which have a major influence on the flow and the resulting heat transfer. Comparison of constant and variable property solutions show substantial differences. In addition, the property variations prevent fully developed flow. The density variation accelerates the fluid in the channels increasing the pressure drop without an accompanying increase in heat flux. Analyses of the inlet configuration suggest that side entry from a manifold can affect the development of the velocity profile because of vortices generated as the flow enters the channel. Current work is focused on studying the effects of channel bifurcation on the flow field and the heat transfer characteristics. Author

HEAT TRANSFER IN ROCKET COMBUSTION CHAMBERS

P. Anderson, G. Cheng, and R. Farmer *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 111-114 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Complexities of liquid rocket engine heat transfer which involve the injector faceplate and film cooled walls are being investigated by computational analysis. A conjugate heat transfer analysis was used to describe localized heating phenomena associated with particular injector configurations and film coolant flows. These components were analyzed, and the analyses verified when appropriate test data were available. The component analyses are being synthesized into an overall flowfield/heat transfer model. A Navier-Stokes flow solver, the FDNS code, was used to make the analyses. Particular attention was given to the representation of the thermodynamic properties of the fluid streams. Unit flow models of specific coaxial injector elements have been developed and are being used to describe the flame structure near the injector faceplate. Derived from text

ADVANCED MATERIALS FOR RADIATION-COOLED ROCKETS

Brian Reed, James Biaglow, and Steven Schneider *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 115-118 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

The most common material system currently used for low thrust, radiation-cooled rockets is a niobium alloy (C-103) with a fused silica coating (R-512A or R-512E) for oxidation protection. However, significant amounts of fuel film cooling are usually required to keep the material below its maximum operating temperature of 1370 C, degrading engine performance. Also the R-512 coating is subject to cracking and eventual spalling after repeated thermal cycling. A new class of high-temperature, oxidation-resistant materials are being developed for radiation-cooled rockets, with the thermal margin to reduce or eliminate fuel film cooling, while still exceeding the life of silicide-coated niobium. Rhenium coated with iridium is the most developed of these high-temperature materials. Efforts are on-going to develop 22 N, 62 N, and 440 N engines composed of these materials for apogee insertion, attitude control, and other functions. There is also a complimentary NASA and industry effort to determine the life limiting mechanisms and characterize the thermomechanical properties of these materials. Other material systems are also being studied which may offer more thermal margin and/or oxidation resistance, such as hafnium carbide/tantalum carbide matrix composites and ceramic oxide-coated iridium/rhenium chambers. MOLECULAR GAS DYNAMICS APPLIED TO LOW-THRUST PROPULSION

Donna Zelesnik (Ohio Aerospace Inst., Brook Park.), Paul F. Penko, and Iain D. Boyd (Cornell Univ., Ithaca, NY.) *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 119-124 (For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

The Direct Simulation Monte Carlo method is currently being applied to study flowfields of small thrusters, including both the internal nozzle and the external plume flow. The DSMC method is employed because of its inherent ability to capture nonequilibrium effects and proper boundary physics in low-density flow that are not readily obtained by continuum methods. Accurate prediction of both the internal and external nozzle flow is important in determining plume expansion which, in turn, bears directly on impingement and contamination effects. Author

COMPUTATIONAL FLUID DYNAMICS (CFD) APPLICATIONS IN ROCKET PROPULSION ANALYSIS AND DESIGN

P. K. McConnaughey, R. Garcia, L. W. Griffin, and J. H. Ruf *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 125-129 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Computational Fluid Dynamics (CFD) has been used in recent applications to affect subcomponent designs in liquid propulsion rocket engines. This paper elucidates three such applications for turbine stage, pump stage, and combustor chamber geometries. Details of these applications include the development of a high turning airfoil for a gas generator (GG) powered, liquid oxygen (LOX) turbopump, single-stage turbine using CFD as an integral part of the design process. CFD application to pump stage design has emphasized analysis of inducers, impellers, and diffuser/volute sections. Improvements in pump stage impeller discharge flow uniformity have been seen through CFD optimization on coarse grid models. In the area of combustor design, recent CFD analysis of a film cooled ablating combustion chamber has been used to quantify the interaction between film cooling rate, chamber wall contraction angle, and geometry and their effects of these quantities on local wall temperature. The results are currently guiding combustion chamber design and coolant flow rate for an upcoming subcomponent test. Critical aspects of successful integration of CFD into the design cycle includes a close-coupling of CFD and design organizations, quick turnaround of parametric analyses once a baseline CFD benchmark has been established, and the use of CFD methodology and approaches that address pertinent design issues. In this latter area, some problem details can be simplified while retaining key physical aspects to maintain analytical integrity. Author (revised)

EFFICIENCY AND RELIABILITY ENHANCEMENTS IN PROPULSION FLOWFIELD MODELING c34

Philip E. O. Buelow, Sankaran Venkateswaran, and Charles L. Merkle *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 130-134 (For primary document see N94-23028 06-20)

Avail: CASI HC A01/MF A03

The implementation of traditional CFD algorithms in practical propulsion related flowfields often leads to dramatic reductions in efficiency and/or robustness. The present research is directed at understanding the reasons for this deterioration and finding methods to circumvent it. Work to date has focussed on low Mach number regions, viscous dominated regions, and high grid aspect ratios. Time derivative preconditioning, improved definition of the local time stepping, and appropriate application of boundary conditions are employed to decrease the required time to obtain a solution, while maintaining accuracy. A number of cases having features typical of rocket engine flowfields are computed to demonstrate the improvement over conventional methods. These cases include laminar and turbulent high Reynolds number flat plate boundary layers, flow over a backward-facing step, a diffusion flame, and wall heat-flux calculations in a turbulent converging-diverging nozzle. Results from these cases show convergence that is virtually independent of the local Mach number and the grid aspect ratio, which translates to a convergence speed-up of up to several orders of magnitude over conventional algorithms. Current emphasis is in extending these results to three-dimensional flows with highly stretched grids.

COMPUTATION OF PROPULSION-RELATED FLOWFIELDS USING UNSTRUCTURED ADAPTIVE MESHES c34

Jonathan M. Weiss and Jayathi Y. Murthy *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 135-139 (For primary document see N94-23028 06-20)

Avail: CASI HC A01/MF A03

In this paper, we describe a computational fluid dynamics (CFD) technique based on unstructured triangular/tetrahedral meshes. A finite-volume scheme is used in conjunction with a multi-stage Runge-Kutta algorithm. Convergence enhancements in the form of dual time-stepping and time-derivative preconditioning are used to overcome the limitations of conventional multi-stage schemes. The method is applied to propulsion-related flows and shown to perform satisfactorily. Author (revised)

DUAL-BELL ALTITUDE COMPENSATING NOZZLES

M. Horn and S. Fisher *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 140-147 (For primary document see N94-23028 06-20)

Avail: CASI HC A02/MF A03

The primary objective of this cold flow test effort was to assess the performance characteristics of dual bell nozzles and to obtain preliminary design criteria by testing a number of configurations. Characteristics of interest included low altitude performance, high altitude performance, and the flow transition process. In combination with this performance data, other factors such as cost, weight, fabricability, and vehicle related issues could then be traded to establish the feasibility of the concept.

FOIL BEARING RESEARCH AT PENN STATE c37

Marc Carpino *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 148-151 (For primary document see N94-23028 06-20)

Avail: CASI HC A01/MF A03

Foil journal bearings consist of a compliant metal shell or foil which supports a rigid journal by means of a fluid film. Foil bearings are considered to be a potential alternative to rolling element or traditional rigid surface bearings in cryogenic turbomachinery applications. The prediction of foil bearing performance requires the coupled solution of the foil deflection and the fluid flow in the bearing clearance between the rotor and the foil. The investigations being conducted in the Department of Mechanical Engineering at Penn State are focused in three areas: theoretical prediction of steady state bearing performance, modeling of the dynamic bearing characteristics to determine performance in rotor systems, and experimental verification of analysis codes. The current status and results from these efforts will be discussed. Author

TWO STAGE TURBINE FOR ROCKETS c37

Joseph P. Veres *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 152-158 (For primary document see N94-23028 06-20)

Avail: CASI HC A02/MF A03

The aerodynamic design and rig test evaluation of a small counter-rotating turbine system is described. The advanced turbine airfoils were designed and tested by Pratt & Whitney. The technology represented by this turbine is being developed for a turbopump to be used in an advanced upper stage rocket engine. The advanced engine will use a hydrogen expander cycle and achieve high performance through efficient combustion of hydrogen/oxygen propellants, high combustion pressure, and high area ratio exhaust nozzle expansion. Engine performance goals require that the turbopump drive turbines achieve high efficiency at low gas flow rates. The low mass flow rates and high operating pressures result in very small airfoil heights and diameters. The high efficiency and small size requirements present a challenging turbine design problem. The shrouded axial turbine blades are 50 percent reaction with a maximum thickness to chord ratio near 1. At 6 deg from the tangential direction, the nozzle and blade exit flow angles are well below the traditional design minimum limits. The blade turning angle of 160 deg also exceeds the maximum limits used in traditional turbine designs. Author (revised)

COMPUTATIONAL FLUID DYNAMIC MODELLING OF CAVITATION c34

Manish Deshpande, Jinzhang Feng, and Charles L. Merkle *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 159-163 (For primary document see N94-23028 06-20)

Avail: CASI HC A01/MF A03

Models in sheet cavitation in cryogenic fluids are developed for use in Euler and Navier-Stokes codes. The models are based upon earlier potential-flow models but enable the cavity inception point, length, and shape to be determined as part of the computation. In the present paper, numerical solutions are compared with experimental measurements for both pressure distribution and cavity length. Comparisons between models are also presented. The CFD model provides a relatively simple modification to an existing code to enable cavitation performance predictions to be included. The analysis also has the added ability of incorporating thermodynamic effects of cryogenic fluids into the analysis. Extensions of the current two-dimensional steady state analysis to three-dimensions and/or time-dependent flows are, in principle, straightforward although geometrical issues become more complicated. Linearized models, however offer promise of providing effective cavitation modeling in three-dimensions. This analysis presents good potential for improved understanding of many phenomena associated with cavity flows. Author (revised)

A TECHNIQUE TO MEASURE ROTORDYNAMIC COEFFICIENTS IN HYDROSTATIC BEARINGS c37

Russell J. Capaldi *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 164-169 (For primary document see N94-23028 06-20)

Avail: CASI HC A02/MF A03

An experimental technique is described for measuring the rotordynamic coefficients of fluid film journal bearings. The bearing tester incorporates a double-spool shaft assembly that permits independent control over the journal spin speed and the frequency of an adjustable-magnitude circular orbit. This configuration yields data that enables determination of the full linear anisotropic rotordynamic coefficient matrices. The dynamic force measurements were made simultaneously with two independent systems, one with piezoelectric load cells and the other with strain gage load cells. Some results are presented for a four-recess, oil-fed hydrostatic journal bearing. Author

COMPUTATION OF FLOWS IN A TURN-AROUND DUCT AND A TURBINE CASCADE USING ADVANCED TURBULENCE MODELS c34
B. Lakshminarayana and J. Luo *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 170-175 (For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

Numerical investigation has been carried out to evaluate the capability of the Algebraic Reynolds Stress Model (ARSM) and the Nonlinear Stress Model (NLSM) to predict strongly curved turbulent flow in a turn-around duct (TAD). The ARSM includes the near-wall damping term of pressure-strain correlation phi(sub ij,w), which enables accurate prediction of individual Reynolds stress components in wall flows. The TAD mean flow quantities are reasonably well predicted by various turbulence models. The ARSM yields better predictions for both the mean flow and the turbulence quantities than the NLSM and the k-epsilon (k = turbulent kinetic energy, epsilon = dissipation rate of k) model. The NLSM also shows slight improvement over the k-epsilon model. However, all the models fail to capture the recovery of the flow from strong curvature effects. The formulation for phi(sub ij,w) appears to be incorrect near the concave surface. The hybrid k-epsilon/ARSM, Chien's k-epsilon model, and Coakley's q-omega (q = the square root of k, omega = epsilon/k) model have also been employed to compute the aerodynamics and heat transfer of a transonic turbine cascade. The surface pressure distributions and the wake profiles are predicted well by all the models. The k-epsilon model and the k-epsilon/ARSM model provide better predictions of heat transfer than the q-omega model. The k-epsilon/ARSM solutions show significant differences in the predicted skin friction coefficients, heat transfer rates and the cascade performance parameters, as compared to the k-epsilon model. The k-epsilon/ARSM model appears to capture, qualitatively, the anisotropy associated with by-pass transition. Author (revised)

BRUSH SEALS FOR CRYOGENIC APPLICATIONS c37
Margaret P. Proctor *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 176-180 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Brush seals are compliant, contacting seals and have significantly lower leakage than labyrinth seals in gas turbine applications. Their characteristics of long life and low leakage make them candidates for use in rocket engine turbopumps. Two-inch diameter brush seals with a nominal 0.005 inch radial interference were tested in liquid nitrogen at shaft speeds up to 35,000 rpm and pressure drops up to 175 psid per seal. A labyrinth seal was also tested to provide a baseline. Performance, staging effects, and wear results are presented. Author

RELIABILITY ENHANCEMENT OF NAVIER-STOKES CODES THROUGH CONVERGENCE ENHANCEMENT c38
K.-Y. Choi and G. S. Dulikravich *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 181-186 (For primary document see N94-23028 06-20)
Avail: CASI HC A02/MF A03

Reduction of total computing time required by an iterative algorithm for solving Navier-Stokes equations is an important aspect of making the existing and future analysis codes more cost effective. Several attempts have been made to accelerate the convergence of an explicit Runge-Kutta time-stepping algorithm. These acceleration methods are based on local time stepping, implicit residual smoothing, enthalpy damping, and multigrid techniques. Also, an extrapolation procedure based on the power method and the Minimal Residual Method (MRM) were applied to the Jameson's multigrid algorithm. The MRM uses same values of optimal weights for the corrections to every equation in a system and has not been shown to accelerate the scheme without multigriding. Our Distributed Minimal Residual (DMR) method based on our General Nonlinear Minimal Residual (GNLMR) method allows each component of the solution vector in a system of equations to have its own convergence speed. The DMR method was found capable of reducing the computation time by 10-75 percent depending on the test case and grid used. Recently, we have developed and tested a new method termed Sensitivity Based DMR or SBMR method that is easier to implement in different codes and is even more robust and computationally efficient than our DMR method. OPTIMIZATION OF ENERGY TRANSFER IN MICROWAVE ELECTROTHERMAL THRUSTERS
D. J. Sullivan and M. M. Micci *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 187-190 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Results are presented from preliminary tests conducted to evaluate the performance of a prototype microwave electrothermal thruster. The primary component of the device is a microwave resonant cavity. The device produces stable axial plasmas within a pressurized section of the cavity with the plasma positioned in the inlet region of the nozzle. Plasma stability is enhanced by axial power coupling, an optimal distribution of electric power density within the cavity, and a propellant gas flow which has a large vortical velocity component. The thruster has been operated with a number of propellant gases: helium, nitrogen, ammonia, and hydrogen. Plasmas can be formed in a reliable manner at cavity pressures of 1 kPa and incident power levels ranging from 50 W to 350 W, depending on the gas used, and can be operated at pressures up to 300 kPa at power levels up to 2200 W. Ideal performance results of vacuum Isp and thermal efficiency vs. specific power are presented for each gas. Representative results of this preliminary work are: He - Isp = 625 s, eta-thermal = 90 percent; N2 - Isp = 270 s, eta-thermal = 41 percent; NH3 - Isp = 475 s, eta-thermal= 55 percent; H2 - Isp = 1040 s, eta-thermal = 53 percent. CFD MODELING OF MICROWAVE ELECTROTHERMAL THRUSTERS
Douglas A. Schwer, S. Venkateswaran, and Charles L. Merkle *In its* NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 191-194 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

Microwave-heated plasmas in convergent nozzles are analyzed using a coupled Maxwell and Navier-Stokes solver to examine relevant issues associated with microwave thermal propulsion. Parametric studies are conducted to understand the effect of power, pressure, and plasma location with respect to the nozzle throat. For nozzles in the 0.5 to 3 N range with helium flow, results show that specific impulses up to 550-650 seconds are possible, with further increases being limited by severe wall-heating. Coupling efficiencies of over 90 percent are consistently obtained, with overall efficiencies ranging from 40 percent to 80 percent. Size scale-up studies-done by scaling the frequency from 2.45 GHz to 0.91 GHz-indicate that plasma migration toward the walls occurs more frequently for the lower frequency. Increasing the cavity aspect ratio and detuning the cavity are found to be effective ways of keeping the plasma on axis. Derived from text

In 1989, a Presidential directive created the Space Exploration Initiative (SEI) which had a goal of placing mankind on Mars in the early 21st century. The SEI was effectively terminated in 1992 with the election of a new administration. Although the initiative did not exist long enough to allow substantial technology development, it did provide a venue, for the first time in 20 years, to comprehensively evaluate advanced propulsion concepts which could enable fast, manned transits to Mars. As part of the SEI based investigations, scientists from NASA, DoE National Laboratories, universities, and industry met regularly and proceeded to examine a variety of innovative ideas. Most of the effort was directed toward developing a solid-core, nuclear thermal rocket and examining a high-power nuclear electric propulsion system. In addition, however, an Innovative Concepts committee was formed and charged with evaluating concepts that offered a much higher performance but were less technologically mature. The committee considered several concepts and eventually recommended that further work be performed in the areas of gas core fission rockets, inertial confinement fusion systems, antimatter based rockets, and gas core fission electric systems. Following the committee's recommendations, some computational modeling work has been performed at Los Alamos in certain of these areas and critical issues have been identified. Derived from text

PERFORMANCE ASSESSMENT OF LOW PRESSURE NUCLEAR THERMAL PROPULSION
Harrold P. Gerrish, Jr. and Glen E. Doughty *In* Pennsylvania State Univ., NASA Propulsion Engineering Research Center, Volume 2 Nov. 1993 p 207-211 (For primary document see N94-23028 06-20)
Avail: CASI HC A01/MF A03

An increase in Isp for nuclear thermal propulsion systems is desirable for reducing the propellant requirements and cost of future applications, such as the Mars Transfer Vehicle. Several previous design studies have suggested that the Isp could be increased substantially with hydrogen dissociation/recombination. Hydrogen molecules (H2), at high temperatures and low pressures, will dissociate to monatomic hydrogen (H). The reverse process (i.e., formation of H2 from H) is exothermic. The exothermic energy in a nozzle increases the kinetic energy and therefore, increases the Isp. The low pressure nuclear thermal propulsion system (LPNTP) system is expected to maximize the hydrogen dissociation/recombination and Isp by operating at high chamber temperatures and low chamber pressures. The process involves hydrogen flow through a high temperature, low pressure fission reactor, and out a nozzle. The high temperature (approximately 3000 K) of the hydrogen in the reactor is limited by the temperature limits of the reactor material. The minimum chamber pressure is about 1 atm because lower pressures decrease the engines thrust to weight ratio below acceptable limits. This study assumes that hydrogen leaves the reactor and enters the nozzle at the 3000 K equilibrium dissociation level. Hydrogen dissociation in the reactor does not affect LPNTP performance like dissociation in traditional chemical propulsion systems, because energy from the reactor resupplies energy lost due to hydrogen dissociation. Recombination takes place in the nozzle due primarily to a drop in temperature as the Mach number increases. However, as the Mach number increases beyond the nozzle throat, the static pressure and density of the flow decreases and minimizes the recombination. The ideal LPNTP Isp at 3000 K and 10 psia is 1160 seconds due to the added energy from fast recombination rates. The actual Isp depends on the finite kinetic reaction rates which affect the amount of monatomic hydrogen recombination before the flow exits the nozzle. A LPNTP system has other technical issues (e.g. flow instability and two-phase flow) besides hydrogen dissociation/recombination which affect the systems practicality. In this study, only the effects of hydrogen dissociation/recombination are examined. Derived from text

AN F2D ANALYSIS OF THE FLOW INSTABILITY TEST (FIT) EXPERIMENT
A. Suo-Anttila 1993 12 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-001420; SAND-93-7080C; CONF-940101-6) Avail: CASI HC A03/MF A01

The F2D code was used to analyze the Flow-Instability-Test (FIT) experiments at Brookhaven National Laboratories. A one-dimensional analysis of the experiment indicated that at the higher temperature levels the element should be unstable. The experimental data corroborated this theory. The two-dimensional simulation behaved in a manner that was very similar to the experimentally measured behavior. In conclusion, the FIT experimental analysis yields partial code validation of F2D, and it also validates the methodology that is used in analyzing thermal flow stability. DOE

(NASA-CR-194812; NAS 1.26:194812) Avail: CASI HC A03/MF A01

This report presents two numerical methods considered for the computation of fuel-optimal, low-thrust orbit transfers in large numbers of burns. The origins of these methods are observations made with the extremal solutions of transfers in small numbers of burns; there seems to exist a trend such that the longer the time allowed to perform an optimal transfer the less fuel that is used. These longer transfers are obviously of interest since they require a motor of low thrust; however, we also find a trend that the longer the time allowed to perform the optimal transfer the more burns are required to satisfy optimality. Unfortunately, this usually increases the difficulty of computation. Both of the methods described use small-numbered burn solutions to determine solutions in large numbers of burns. One method is a homotopy method that corrects for problems that arise when a solution requires a new burn or coast arc for optimality. The other method is to simply patch together long transfers from smaller ones. An orbit correction problem is solved to develop this method. This method may also lead to a good guidance law for transfer orbits with long transfer times. Author

REDUCTION OF THE ANODE FALL IN A COAXIAL PLASMA THRUSTER WITH AN APPLIED MAGNETIC NOZZLE
J. T. Scheuer, R. P. Hoyt, K. F. Schoenberg, R. A. Gerwin, R. W. Moses, I. Henins, R. M. Mayo (North Carolina State Univ., Raleigh.), and D. C. Black (North Carolina State Univ., Raleigh.) 1993 8 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract W-7405-eng-36)
(DE94-000670; LA-UR-93-3518; CONF-940101-8) Avail: CASI HC A02/MF A01 (US Sales Only)

The Coaxial Thruster Experiment at the Los Alamos National Laboratory has demonstrated 10 ms quasi-steady operation and ideal magnetohydrodynamic (MHD)-like performance. Previous experiments utilized an unoptimized applied magnetic configuration in which field lines intercepted both thruster electrodes. These experiments demonstrated the ability of magnetic connection between the plasma and the electrodes to control the anode fall. The effect of an evolved applied magnetic nozzle which provides magnetic connection of the electrodes to the bulk of the plasma without direct magnetic connection of the electrodes is reported. This magnetic nozzle configuration significantly reduces the anode fall fraction and thus may provide a promising means of improving magnetoplasmadynamic (MPD) thruster efficiency. DOE

CONTAMINATION CONTROL AND PLUME ASSESSMENT OF LOW-ENERGY THRUSTERS
John J. Scialdone May 1993 8 p
(NASA-TM-104585; 93E01024; NAS 1.15:104585) Avail: CASI HC A02/MF A01

Potential contamination of a spacecraft cryogenic surface by a xenon (Xe) ion generator was evaluated. The analysis involves the description of the plume exhausted from the generator with its relative component fluxes on the spacecraft surfaces, and verification of the conditions for condensation, adsorption, and sputtering at those locations. The data describing the plume fluxes and their effects on surfaces were obtained from two sources: the tests carried out with the Xe generator in a small vacuum chamber to indicate deposits and sputter on monitor slides; and the extensive tests with a mercury (Hg) ion thruster in a large vacuum chamber. The Hg thruster tests provided data on the neutrals, on low-energy ion fluxes, on high-energy ion fluxes, and on sputtered materials at several locations within the plume. Author (revised)

TRANSPARENT CONDUCTING THIN FILMS FOR SPACECRAFT APPLICATIONS
Marla E. Perez-Davis, Tania Malave-Sanabria (Ohio Aerospace Inst., Brook Park.), Paul Hambourger (Cleveland State Univ., OH.), Sharon K. Rutledge, David Roig (Cleveland State Univ., OH.), Kim K. deGroh, and Ching-Cheh Hung Jan. 1994 8 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(Contract NCC3-19; RTOP 506-41-41)
(NASA-TM-106466; E-8332; NAS 1.15:106466; AIAA Paper 94-0375) Copyright Avail: CASI HC A02/MF A01

Transparent conductive thin films are required for a variety of optoelectronic applications: automotive and aircraft windows, and solar cells for space applications. Transparent conductive coatings of indium-tin-oxide (ITO)-magnesium fluoride (MgF2) and aluminum doped zinc oxide (AZO) at several dopant levels are investigated for electrical resistivity (sheet resistance), carrier concentration, optical properties, and atomic oxygen durability. The sheet resistance values of ITO-MgF2 range from 102 to 1011 ohms/square, with transmittance of 75 to 86 percent. The AZO films sheet resistances range from 107 to 1011 ohms/square with transmittances from 84 to 91 percent. It was found that in general, with respect to the optical properties, the zinc oxide (ZnO), AZO, and the high MgF2 content ITO-MgF2 samples, were all durable to atomic oxygen plasma, while the low MgF2 content of ITO-MgF2 samples were not durable to atomic oxygen plasma exposure. NASA LeRC is developing a 30 cm diameter xenon ion thruster for auxiliary and primary propulsion applications. To maximize expectations for user-acceptance of ion propulsion technology, NASA LeRC, through their Electric Propulsion Outreach Program, is providing sectors of industry with portable power consoles for operation of 5 KW-class xenon ion thrusters. This power console provides all necessary functions to permit thruster operations over a 0.5-5 KW envelope under both manual and automated control. These functions include the following: discharge, cathode heater, neutralizer keeper, and neutralizer heater currents, screen and accelerator voltages, and a gas feed system to regulate and control propellant flow to the thruster. An electronic circuit monitors screen and accelerator currents and controls arcing events. The power console was successfully integrated with the NASA 30 cm thruster. Author (revised)

ASSESSMENT OF AN SP-100 BI-MODAL PROPULSION AND POWER SYSTEM
J. J. Buksa, S. DeMuth, and T. Huber (Naval Academy, Annapolis, MD.) 1993 11 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract W-7405-eng-36)
(DE94-000889; LA-UR-93-3324; CONF-940101-4) Avail: CASI HC A03/MF A01 (US Sales Only)

The attractiveness of using the SP-100 space nuclear power system for both electric power production and direct thermal propulsion is discussed. A conceptual modification to the SP-100 generic flight system that uses its hot, primary coolant to directly heat hydrogen propellant is presented. An analytical model of the system and its orbital-mechanical behavior is presented and used to assess the benefits of a number of orbital transfer missions. Both a 500 kW and a 2.4 MW system are assessed. Preliminary results indicate that for LEO-to-GEO transfers, the SP-100 bimodal system offers a 100% increase in payload over conventional chemical-only propulsion systems with transfer times on the order of days. DOE

INVESTIGATION OF A SUBSONIC-ARC-ATTACHMENT THRUSTER USING SEGMENTED ANODES
Darren H. Berns (Minnesota Univ., Minneapolis.), John M. Sankovic, and Charles J. Sarmiento Dec. 1993 25 p Presented at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE See also A93-49769
(RTOP 506-42-31)
(NASA-TM-106419; E-7790; NAS 1.15:106419; AIAA Paper 93-1899)
Avail: CASI HC A03/MF A01

To investigate high frequency arc instabilities observed in subsonic-arc-attachment thrusters, a 3 kW, segmented-anode arc jet was designed and tested using hydrogen as the propellant. The thruster nozzle geometry was scaled from a 30 kW design previously tested in the 1960's. By observing the current to each segment and the arc voltage, it was determined that the 75-200 kHz instabilities were results of axial movements of the arc anode attachment point. The arc attachment point was fully contained in the subsonic portion of the nozzle for nearly all flow rates. The effects of isolating selected segments were investigated. In some cases, forcing the arc downstream caused the restrike to cease. Finally, decreasing the background pressure from 18 to 0.05 Pa affected the pressure distribution in the nozzle including the pressure in the subsonic arc chamber. Author (revised)

LOW POWER GROUND-BASED LASER ILLUMINATION FOR ELECTRIC PROPULSION APPLICATIONS Final Report
Michael R. LaPointe and Steven R. Oleson Jan. 1994 28 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA, AIDAA, DGLR, and JSASS
(Contract NAS3-25266; RTOP 506-42-31)
(NASA-CR-194444; NAS 1.26:194444; IEPC-93-208) Avail: CASI HC A03/MF A01

A preliminary evaluation of low power, ground-based laser powered electric propulsion systems is presented. A review of available and near-term laser, photovoltaic, and adaptive optic systems indicates that approximately 5-kW of ground-based laser power can be delivered at an equivalent one-sun intensity to an orbit of approximately 2000 km. Laser illumination at the proper wavelength can double photovoltaic array conversion efficiencies compared to efficiencies obtained with solar illumination at the same intensity, allowing a reduction in array mass. The reduced array mass allows extra propellant to be carried with no penalty in total spacecraft mass. The extra propellant mass can extend the satellite life in orbit, allowing additional revenue to be generated. A trade study using realistic cost estimates and conservative ground station viewing capability was performed to estimate the number of communication satellites which must be illuminated to make a proliferated system of laser ground stations economically attractive. The required number of satellites is typically below that of proposed communication satellite constellations, indicating that low power ground-based laser beaming may be commercially viable. However, near-term advances in low specific mass solar arrays and high energy density batteries for LEO applications would render the ground-based laser system impracticable. Author (revised)

PERFORMANCE EVALUATION OF THE RUSSIAN SPT-100 THRUSTER AT NASA LeRC
John M. Sankovic, John A. Hamley, and Thomas W. Haag Jan. 1994 25 p Presented at the 23rd IEPC Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA, AIDAA, DGLR, and JSASS
(RTOP 506-42-31)
(NASA-TM-106401; E-8235; NAS 1.15:106401; IEPC-93-094) Avail: CASI HC A03/MF A01

Performance measurements of a Russian flight-model SPT-100 thruster were obtained as part of a comprehensive program to evaluate engineering issues pertinent to integration with Western spacecraft. Power processing was provided by a US Government developed laboratory power conditioner. When received the thruster had been subjected to only a few hours of acceptance testing by the manufacturer. Accumulated operating time during this study totalled 148 h and included operation of both cathodes. Cathode flow fraction was controlled both manually and using the flow splitter contained within the supplied xenon flow controller. Data were obtained at current levels ranging from 3 A to 5 A and thruster voltages ranging from 200 V to 300 V. Testing centered on the design power of 1.35 kW with a discharge current of 4.5 A. The effects of facility pressure on thruster operation were examined by varying the pressure via injection of xenon into the vacuum chamber. The facility pressure had a significant effect on thruster performance and stability at the conditions tested. Periods of current instabilities were noted throughout the testing period and became more frequent as testing progressed. Performance during periods of stability agreed with previous data obtained in Russian laboratories. Author

(Contract NAS3-25808)
(NASA-CR-191132; NAS 1.26:191132) Avail: CASI HC A08/MF A02

NASA LeRC is currently developing a FORTRAN based computer model of a complete nuclear electric propulsion (NEP) vehicle that can be used for piloted and cargo missions to the Moon or Mars. Proposed designs feature either a Brayton or a K-Rankine power conversion cycle to drive a turbine coupled with rotary alternators. Both ion and magnetoplasmodynamic (MPD) thrusters will be considered in the model. In support of the NEP model, Rocketdyne is developing power conversion, heat rejection, and power management and distribution (PMAD) subroutines. The subroutines will be incorporated into the NEP vehicle model which will be written by NASA LeRC. The purpose is to document the heat pipe cooled heat rejection subsystem model and its supporting subroutines. The heat pipe cooled heat rejection subsystem model is designed to provide estimate of the mass and performance of the equipment used to reject heat from Brayton and Rankine cycle power conversion systems. The subroutine models the ductwork and heat pipe cooled manifold for a gas cooled Brayton; the heat sink heat exchanger, liquid loop piping, expansion compensator, pump and manifold for a liquid loop cooled Brayton; and a shear flow condenser for a K-Rankine system. In each case, the final heat rejection is made by way of a heat pipe radiator. The radiator is sized to reject the amount of heat necessary. Author (revised)

STATIONARY PLASMA THRUSTER PLUME CHARACTERISTICS Final Report
Roger M. Myers and David H. Manzella Feb. 1994 22 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA
(Contract NAS3-25266; RTOP 506-42-31)
(NASA-CR-194454; E-840626; NAS 1.26:194454) Avail: CASI HC A03/MF A01

Stationary Plasma Thrusters (SPT's) are being investigated for application to a variety of near-term missions. This paper presents the results of a preliminary study of the thruster plume characteristics which are needed to assess spacecraft integration requirements. Langmuir probes, planar probes, Faraday cups, and a retarding potential analyzer were used to measure plume properties. For the design operating voltage of 300 V the centerline electron density was found to decrease from approximately 1.8 x 10 exp 17 cubic meters at a distance of 0.3 m to 1.8 X 10 exp 14 cubic meters at a distance of 4 m from the thruster. The electron temperature over the same region was between 1.7 and 3.5 eV. Ion current density measurements showed that the plume was sharply peaked, dropping by a factor of 2.6 within 22 degrees of centerline. The ion energy 4 m from the thruster and 15 degrees off-centerline was approximately 270 V. The thruster cathode flow rate and facility pressure were found to strongly affect the plume properties. In addition to the plume measurements, the data from the various probe types were used to assess the impact of probe design criteria Author (revised)

HEAT TRANSFER IN ROCKET ENGINE COMBUSTION CHAMBERS AND REGENERATIVELY COOLED NOZZLES Final Report
16 Nov. 1993 169 p Original contains color illustrations
(Contract NAS8-38961)
(NASA-CR-195094; NAS 1.26:195094; SECA-FR-93-18) Avail: CASI HC A08/MF A02; 35 functional color pages

A conjugate heat transfer computational fluid dynamics (CFD) model to describe regenerative cooling in the main combustion chamber and nozzle and in the injector faceplate region for a launch vehicle class liquid rocket engine was developed. An injector model for sprays which treats the fluid as a variable density, single-phase media was formulated, incorporated into a version of the FDNS code, and used to simulate the injector flow typical of that in the Space Shuttle Main Engine (SSME). Various chamber related heat transfer analyses were made to verify the predictive capability of the conjugate heat transfer analysis provided by the FDNS code. The density based version of the FDNS code with the real fluid property models developed was successful in predicting the streamtube combustion of individual injector elements. Author (revised)

IMPROVED GAS CORE PROPULSION MODEL
J. E. Tanner 1993 7 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994.
(Contract DE-AC07-84ID-12435)
(DE94-000929; WINCO-11981; CONF-940101-13) Avail: CASI HC A02/MF A01 (US Sales Only)

A thermodynamic, radiation transport model of a gas core nuclear propulsion reactor has been developed in one-dimensional, spherical geometry, which satisfies local energy balance and allows for arbitrary variation of fuel/propellant ratio and flow rate as functions of radius. Initial cases calculated yield specific impulses of about 1150 sec, but very low thrusts ranging 5-10 kN. DOE

ASSESSMENT OF IMPACT DAMAGE OF COMPOSITE ROCKET MOTOR CASES Final Report, 1 Nov. 1993 - 28 Feb. 1994
Henry G. Paris 19 Feb. 1994 38 p
(Grant NAG8-1016)
(NASA-CR-195143; NAS 1.26:195143) Avail: CASI HC A03/MF A01

This contract reviewed the available literature on mechanisms of low velocity impact damage in filament wound rocket motor cases, NDE methods to quantify damage, critical coupon level test methods, manufacturing and material process variables and empirical and analytical modeling off impact damage. The critical design properties for rocket motor cases are biaxial hoop and axial tensile strength. Low velocity impact damage is insidious because it can create serious nonvisible damage at very low impact velocities. In thick rocket motor cases the prevalent low velocity impact damage is fiber fracture and matrix cracking adjacent to the front face. In contrast, low velocity loading of thin wall cylinders induces flexure, depending on span length and the flexure induces delamination and tensile cracking on the back face wall opposed to impact occurs due to flexural stresses imposed by impact loading. Important NDE methods for rocket motor cases are non-contacting methods that allow inspection from one side. Among these are vibrothermography, and pulse-echo methods based on acoustic-ultrasonic methods. High resolution techniques such as x-ray computed tomography appear to have merit for accurate geometrical characterization of local damage to support development of analytical models of micromechanics. The challenge of coupon level testing is to reproduce the biaxial stress state that the full scale article experiences, and to determine how to scale the composite structure to model full sized behavior. Biaxial tensile testing has been performed by uniaxially tensile loading internally pressurized cylinders. This is experimentally difficult due to gripping problems and pressure containment. Much prior work focused on uniaxial tensile testing of model filament wound cylinders. Interpretation of the results of some studies is complicated by the fact that the fabrication process did not duplicate full scale manufacturing. It is difficult to scale results from testing subscale cylinders since there are significant differences in out time of the resins relative to full scale cylinder fabrication, differences in hoop fiber tensioning and unsatisfactory coupon configurations. It appears that development of a new test method for subscale cylinders is merited. Damage tolerance may be improved by material optimization that uses fiber treatments and matrix modifications to control the fiber matrix interface bonding. It is difficult to develop process optimization in subscale cylinders without also modeling the longer out times resins experience in full scale testing. A major breakthrough in characterizing the effect of impact damage on residual strength, and understanding how to scale results of subscale evaluations, will be a sound micromechanical model that described progressive failure of the composite. Such models will utilize a three dimensional stress analysis due to the complex nature of low velocity impact stresses in thick composites. When these models are coupled with non-contact NDE methods that geometrically characterize the damage and acoustic methods that characterize the effective local elastic properties, accurate assessment of residual strength from impact damage may be possible. Directions for further development are suggested. Author

POWER GENERATION TECHNOLOGY OPTIONS FOR A MARS MISSION
John M. Bozek and Robert L. Cataldo Jan. 1994 8 p Presented at the Symposia on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994; sponsored by University of New Mexico
(RTOP 233-02-0B)
(NASA-TM-106451; E-8310; NAS 1.15:106451) Avail: CASI HC A02/MF A01

The power requirements and resultant power system performances of an aggressive Mars mission are characterized. The power system technologies discussed will support both cargo and piloted space transport vehicles as well as a six-person crew on the Martian surface for 600 days. The mission uses materials transported by cargo vehicles and materials produced using in-situ planetary feed stock to establish a life-support cache and infrastructure for the follow-on piloted lander. Numerous power system technical options are sized to meet the mission power requirements using conventional and solar, nuclear, and wireless power transmission technologies for stationary, mobile surface, and space applications. Technology selections will depend on key criteria such as mass, volume, area, maturity, and application flexibility. Author

NUMERICAL SIMULATION OF CYLINDRICAL, SELF-FIELD MPD THRUSTERS WITH MULTIPLE PROPELLANTS Final Report
Michael R. LaPointe Mar. 1994 21 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 1993; sponsored by ASC, AIAA, DGLR, AIDAA, and JSASS
(Contract NAS3-25266; RTOP 506-42-81)
(NASA-CR-194458; E-8481; NAS 1.26:194458) Avail: CASI HC A03/MF A01

A two-dimensional, two-temperature, single fluid MHD code was used to predict the performance of cylindrical, self-field magnetoplasmadynamic (MPD) thrusters operated with argon, lithium, and hydrogen propellants. A thruster stability equation was determined relating maximum stable J(sup 2)/m values to cylindrical thruster geometry and propellant species. The maximum value of J(sup 2)/m was found to scale as the inverse of the propellant molecular weight to the 0.57 power, in rough agreement with limited experimental data which scales as the inverse square root of the propellant molecular weight. A general equation which relates total thrust to electromagnetic thrust, propellant molecular weight, and J(sup 2)/m was determined using reported thrust values for argon and hydrogen and calculated thrust values for lithium. In addition to argon, lithium, and hydrogen, the equation accurately predicted thrust for ammonia at sufficiently high J(sup 2)/m values. A simple algorithm is suggested to aid in the preliminary design of cylindrical, self-field MPD thrusters. A brief example is presented to illustrate the use of the algorithm in the design of a low power MPD thruster. Author (revised)

For electric propulsion devices to be considered for use on communications satellites, integration impacts must be examined in detail. Two phenomena of concern associated with highly energetic plumes are contamination via sputtered material from the thruster and sputter erosion of downstream surfaces. In order to characterize the net effect of both phenomena, an array of witness plates were mounted in several types of holders and were exposed to the SPT-100 thruster plume for 50 hours. Surface analysis of the witness plates revealed that in the most energetic regions of the plume, there was a net removal of material from the samples facing the thruster. In the peripheral regions, net deposits were observed and characterized by the changes in optical properties of these samples. Changes in surface properties of samples located in collimators were within experimental uncertainty. Author

A 30 cm diameter xenon ion thruster is under development at NASA to provide an ion propulsion option for missions of national interest, and is being proposed for use on the USAF/TRW Space Surveillance, Tracking and Autonomous Repositioning (SSTAR) platform to validate ion propulsion. The thruster incorporates innovations in design, materials, and fabrication techniques compared to those employed in conventional ion thrusters. Specific development efforts include thruster design optimizations, component life testing and validation, vibration testing, and performance characterizations. Under this test program, the ion thruster will be brought to engineering model development status. This paper discusses the performance and power throttling test data for the NASA 30 cm diameter xenon ion thruster over an input power envelope of 0.7 to 4.9 kW, and corresponding thruster lifetime expectations. EMBODIMENT DESIGN FOR A MULTIPROPELLANT RESISTOJET
Johnny Bao, Thierry Chilosi, Jason Goodwin, Jim Mocio, and Bruce Yeh 3 May 1993 59 p
(Contract NASw-4435)
(NASA-CR-195505; NAS 1.26:195505) Avail: CASI HC A04/MF A01

This document presents the design of a multipropellant resistojet to use as an auxiliary propulsion system on the Space Station. Such a system is necessary to counteract atmospheric drag effects encountered by the Station in its orbit. NASA specifications are strictly followed with emphasis on reliability, operating life, multipropellant capability, and exhaust emission control. Several design variants are considered, and the final solution is a resistojet with an electronic pressure regulator, variable control, an internal flow heater, and a conical nozzle. To construct the resistojet, the important components are resolved independently and then integrated with secondary units. The document also includes engineering drawings of the final design with assembly instructions. Before final utilization, a prototype testing is recommended to uncover possible problems. DESIGN OF A RESISTOJET FOR SPACE STATION FREEDOM
Jose Garza, Jill Reisman, Jose Tapia, and Anthony Wright 3 May 1993 53 p
(Contract NASw-4435)
(NASA-CR-195506; NAS 1.26:195506) Avail: CASI HC A04/MF A01

In the mid 1990's, NASA will begin assembly of Space Station Freedom, a permanent outpost in a low-earth orbit. For the station to remain in that orbit, an altitude control system must be developed to resist the effects of atmospheric drag. One system being considered by NASA is called a resistojet, and it uses highly pressurized waste gases heated by electrical resistance to provide thrust on the order of 1 Newton. An additional function of the resistojet is to vent waste gases used by the station and its inhabitants. This report focuses on resolving the issues of system performance, flow and heater control, and materials selection and designing test procedures to resolve, by experimentation, any remaining issues. The conceptual model of the resistojet consists of a shell wrapped by a resistive coil with gases flowing internally through the tube with additional components such as regulators, transducers, and thermocouples. For system performance, the major parameters were calculated from the desired thrust range, the pressure within the resistojet and the cold flow mode of operation; waste gases were analyzed at 100 percent capacity and between 58.95 kPa and 552 kPa. The design team found that any ventilation under all conditions would produce thrust, and therefore, it was decided to limit the design of the ventilation function. The design team proceeded with a simplified model to determine the nozzle throat diameter and chamber diameter. Author (revised)

STE THRUST CHAMBER TECHNOLOGY: MAIN INJECTOR TECHNOLOGY PROGRAM AND NOZZLE ADVANCED DEVELOPMENT PROGRAM (ADP) Final Report
31 Oct. 1993 411 p
(Contract NAS8-37490)
(NASA-CR-193919; NAS 1.26:193919; FR-23116) Avail: CASI HC A18/MF A04

The purpose of the STME Main Injector Program was to enhance the technology base for the large-scale main injector-combustor system of oxygen-hydrogen booster engines in the areas of combustion efficiency, chamber heating rates, and combustion stability. The initial task of the Main Injector Program, focused on analysis and theoretical predictions using existing models, was complemented by the design, fabrication, and test at MSFC of a subscale calorimetric, 40,000-pound thrust class, axisymmetric thrust chamber operating at approximately 2,250 psi and a 7:1 expansion ratio. Test results were used to further define combustion stability bounds, combustion efficiency, and heating rates using a large injector scale similar to the Pratt & Whitney (P&W) STME main injector design configuration including the tangential entry swirl coaxial injection elements. The subscale combustion data was used to verify and refine analytical modeling simulation and extend the database range to guide the design of the large-scale system main injector. The subscale injector design incorporated fuel and oxidizer flow area control features which could be varied; this allowed testing of several design points so that the STME conditions could be bracketed. The subscale injector design also incorporated high-reliability and low-cost fabrication techniques such as a one-piece electrical discharged machined (EDMed) interpropellant plate. Both subscale and large-scale injectors incorporated outer row injector elements with scarfed tip features to allow evaluation of reduced heating rates to the combustion chamber. Author (revised)

Russian electric propulsion technologies have recently become available on the world market. Of significant interest is the Stationary Plasma Thruster

(SPT) which has a significant flight heritage in the former Soviet space program. The SPT has performance levels of up to 1600 seconds of specific impulse at a thrust efficiency of 0.50. Studies have shown that this level of performance is well suited for stationkeeping applications, and the SPT-100, with a 1.35 kW input power level, is presently being evaluated for use on Western commercial satellites. Under a program sponsored by the Innovative Science and Technology Division of the Ballistic Missile Defense Organization, a team of U.S. electric propulsion specialists observed the operation of the SPT-100 in Russia. Under this same program, power electronics were developed to operate the SPT-100 to characterize thruster performance and operation in the U.S. The power electronics consisted of a discharge, cathode heater, and pulse igniter power supplies to operate the thruster with manual flow control. A Russian designed matching network was incorporated in the discharge supply to ensure proper operation with the thruster. The cathode heater power supply and igniter were derived from ongoing development projects. No attempts were made to augment thruster electromagnet current in this effort. The power electronics successfully started and operated the SPT-100 thruster in performance tests at NASA Lewis, with minimal oscillations in the discharge current. The efficiency of the main discharge supply was measured at 0.92, and straightforward modifications were identified which could increase the efficiency to 0.94. Author (revised)

A hollow cathode plasma contactor has been baselined as a charge control device for the Space Station (SS) to prevent deleterious interactions of coated structural components with the ambient plasma. NASA LeRC Work Package 4 initiated the development of a plasma contactor system comprised of a Power Electronics Unit (PEU), an Expellant Management Unit (EMU), a command and data interface, and a Plasma Contactor Unit (PCU). A breadboard PEU was designed and fabricated. The breadboard PEU contains a cathode heater and discharge power supply, which were required to operate the PCU, a control and auxiliary power converter, an EMU interface, a command and telemetry interface, and a controller. The cathode heater and discharge supplies utilized a push-pull topology with a switching frequency of 20 kHz and pulse-width-modulated (PWM) control. A pulse ignition circuit derived from that used in arcjet power processors was incorporated in the discharge supply for discharge ignition. An 8088 based microcontroller was utilized in the breadboard model to provide a flexible platform for controller development with a simple command/data interface incorporating a direct connection to SS Mulitplexer/Demultiplexer (MDM) analog and digital I/O cards. Incorporating this in the flight model would eliminate the hardware and software overhead associated with a 1553 serial interface. The PEU autonomously operated the plasma contactor based on command inputs and was successfully integrated with a prototype plasma contactor unit demonstrating reliable ignition of the discharge and steady-state operation. THEORETICAL CONSIDERATIONS FOR REACTION-FORMED SILICON CARBIDE (RFSC) FORMATION BY MOLTEN SILICON INFILTRATION INTO SLURRY-DERIVED PREFORMS

D. R. Behrendt and M. Singh Dec. 1993 11 p

(RTOP 537-04-20)

(NASA-TM-106414; E-8250; NAS 1.15:106414) Avail: CASI HC A03/MF A01

For reaction-formed silicon carbide (RFSC) ceramics produced by silicon melt infiltration of porous carbon preforms, equations are developed to relate the amount of residual silicon to the initial carbon density. Also, for a slurry derived preform containing both carbon and silicon powder, equations are derived which relate the amount of residual silicon in the RFSC to the relative density of the carbon in the preform and to the amount of silicon powder added to the slurry. For a porous carbon preform that does not have enough porosity to prevent choking-off of the silicon infiltration, these results show that complete silicon infiltration can occur by adding silicon powder to the slurry mixture used to produce these preforms. A METHOD TO REMOVE INTERCALATES FROM BROMINE AND IODINE INTERCALATED CARBON FIBERS

Ching-cheh Hung Dec. 1993 9 p Presented at the 21st Biennial Conference on Carbon, Buffalo, NY, 13-18 Jun. 1993; sponsored by the American Carbon Society
(RTOP 505-41-41)
(NASA-TM-106443; E-8287; NAS 1.15:16443) Avail: CASI HC A02/MF A01

Upon exposure to room-temperature fluorine, intercalated carbon fibers (containing either bromine alone or iodine and bromine together) become heavier and less stable. For Amoco P-100 graphitized carbon fibers which were intercalated with 18 percent bromine by weight, 1 hr of fluorine exposure results in a large weight increase, but causes only a small decrease in thermal stability. More than I hr of fluorine exposure time results in small additional increases in fiber weight, but significant further decreases in fiber thermal stability. Such phenomena do not occur if the fluorine exposure is at 250 C. These observations suggest the mechanism that at room temperature, fluorine is absorbed quickly by the intercalated fibers and intercalated slowly into the fibers. Most of the original intercalates are replaced by fluorine in the process of fluorine intercalation. Under an inert environment, the bromine intercalated fibers are much more thermally stable. After 800 C vacuum heating for two weeks, the brominated fibers lost about 45 percent of their bromine, and their resistivity increased from 64 omega-cm to a range of 95 to 170 micro omega-cm. This is still much lower than the 300 micro omega-cm value for pristine P-100. For practical purposes, in order to preserve their thermal stability, brominated fibers need to be protected from exposure to fluorine at room temperature, or to any intercalate at a temperature where, upon direct contact to graphite, an intercalation compound can easily be formed. ORDERED ORGANIC THIN FILMS SELF-ASSEMBLED FROM THE VAPOR PHASE c27

M. K. Debe *In* NASA. Marshall Space Flight Center, Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 11-15 (For primary document see N94-24338 06-23)
Avail: CASI HC A01/MF A03

Organic films self-assembled from a liquid phase, as in Langmuir-Blodgett or adsorption from solution, have received much attention in the past decade as techniques to achieve highly oriented-ordered polymeric thin films. Many organic compounds including some of the same fatty acids have been vapor deposited as well. However, organic pigments and dyes comprise a major class of important materials which have very low solubilities yet excellent thermal stabilities, making them ideally suited for film deposition from the vapor phase. Surprisingly, such molecular systems exhibit a significant propensity to self order, a high sensitivity to deposition parameters, and a range of microstructural forms that cannot be duplicated by the less energetic mechanisms associated with solution adsorption processes. Molecular solids such as heterocyclic polynuclear aromatics are excellent candidates for film formation by vacuum deposition means. Over the past decade, our work and that of others investigating a wide variety of perylene and phthalocyanine derivatives identified five deposition parameters that can significantly affect film morphology, physical microstructure, and type and extent of ordering developed in vacuum and vapor transport grown films. These parameters are substrate temperature, deposition rate, substrate chemistry and epitaxy, ambient gas convective flows, and post deposition annealing. Examples of how each of these conditions manifest themselves in the film structure and ordering, most frequently revealed by scanning electron microscopy, reflection absorption infrared spectroscopy (RAIR), and grazing incidence x-ray diffraction (GIX), are presented. NUMERICAL MODELING OF PHYSICAL VAPOR TRANSPORT UNDER MICROGRAVITY CONDITIONS: EFFECT OF THERMAL CREEP AND STRESS c29

Daniel W. Mackowski and Roy W. Knight *In* NASA. Marshall Space Flight Center, Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 17-20 (For primary document see N94-24338 06-23)
Avail: CASI HC A01/MF A03

One of the most promising applications of microgravity (micro-g) environments is the manufacture of exotic and high-quality crystals in closed cylindrical ampoules using physical vapor transport (PVT) processes. The quality enhancements are believed to be due to the absence of buoyant convection in the weightless environment - resulting in diffusion-limited transport of the vapor. In a typical experiment, solid-phase sample material is initially contained at one end of the ampoule. The sample is made to sublime into the vapor phase and deposit onto the opposite end by maintaining the source at an elevated temperature with respect to the deposit. Identification of the physical factors governing both the rates and uniformity of crystal growth, and the optimization of the micro-g technology, will require an accurate modeling of the vapor transport within the ampoule. Previous micro-g modeling efforts have approached the problem from a 'classical' convective/diffusion formulation, in which convection is driven by the action of buoyancy on thermal and solutal density differences. The general conclusion of these works have been that in low gravity environments the effect of buoyancy on vapor transport is negligible, and vapor transport occurs in a diffusion-limited mode. However, it has been recently recognized than in the non-isothermal (and often low total pressure) conditions encountered in ampoules, the commonly-assumed no-slip boundary condition to the differential equations governing fluid motion can be grossly unrepresentative of the actual situation. Specifically, the temperature gradients can give rise to thermal creep flows at the ampoule side walls. In addition, temperature gradients in the vapor itself can, through the action of thermal stress, lead to bulk fluid convection. Author (revised)

ELECTRIC FIELD-MEDIATED PROCESSING OF POLYMER BLEND SOLUTIONS c27

G. E. Wnek and S. Krause *In* NASA. Marshall Space Flight Center, Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 21-23 (For primary document see N94-24338 06-23)
Avail: CASI HC A01/MF A03

Multiphase polymer blends in which the minor phases are oriented in a desired direction may demonstrate unique optical, electrical, and mechanical properties. While morphology development in shear fields was studied extensively, little work has focused on effects of electric fields on phase structure. The use of electric fields for blend morphology modulation with particular attention given to solvent casting of blends in d.c. fields was explored. Both homopolymer blends (average phase sizes of several microns) and diblock copolymer/homopolymer blends (average phase sizes of hundreds of Angstroms) were investigated. Summarized are important observations and conclusions. Author (revised)

DEFECTS IN ELECTRO-OPTICALLY ACTIVE POLYMER SOLIDS c27

David C. Martin *In* NASA. Marshall Space Flight Center, Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 25-43 (For primary document see N94-24338 06-23)
Avail: CASI HC A03/MF A03

There is considerable current interest in the application of organic and polymeric materials for electronic and photonic devices. The rapid, non-linear optical (NLO) response of these materials makes them attractive candidates for waveguides, interferometers, and frequency doublers. In order to realize the full potential of these systems, it is necessary to develop processing schemes which can fabricate these molecules into ordered arrangements. There is enormous potential for introducing well-defined, local variations in microstructure to control the photonic properties of organic materials by rational 'defect engineering.' This effort may eventually become as technologically important as the manipulation of the electronic structure of solid-state silicon based devices is at present. The success of this endeavor will require complimentary efforts in the synthesis, processing, and characterization of new materials. Detailed information about local microstructure will be necessary to understand the influence of symmetry breaking of the solid phases near point, line, and planar defects. In metallic and inorganic polycrystalline materials, defects play an important role in modifying macroscopic properties. To understand the influence of particular defects on the properties of materials, it has proven useful to isolate the defect by creating bicrystals between two-component single crystals. In this way the geometry of a grain boundary defect and its effect on macroscopic properties can be determined unambiguously. In crystalline polymers it would be valuable to establish a similar depth of understanding about the relationship between defect structure and macroscopic properties. Conventionally processed crystalline polymers have small crystallites (10-20 nm), which implies a large defect density in the solid state. Although this means that defects may play an important or even dominant role in crystalline or liquid crystalline polymer systems, it also makes it difficult to isolate the effect of a particular boundary on a macroscopically observed property. However, the development of solid-state and thin-film polymerization mechanisms have facilitated the synthesis of highly organized and ordered polymers. These systems provide a unique opportunity to isolate and investigate in detail the structure of covalently bonded solids near defects and the effect of these defects on the properties of the material. The study of defects in solid polymers has been the subject of a recent review (Martin, 1993). Derived from text

PREDICTION OF NONLINEAR OPTICAL PROPERTIES OF ORGANIC MATERIALS. GENERAL THEORETICAL CONSIDERATIONS Abstract Only c74

B. Cardelino (Atlanta Univ. Center, Inc., GA.), C. Moore, and S. Zutaut (Alabama Univ., Huntsville.) *In its* Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 45-46 (For primary document see N94-24338 06-23)

Avail: CASI HC A01/MF A03

The prediction of nonlinear optical properties of organic materials is geared to assist materials scientists in the selection of good candidate molecules. A brief summary of the quantum mechanical methods used for estimating hyperpolarizabilities will be presented. The advantages and limitations of each technique will be discussed. Particular attention will be given to the finite-field method for calculating first and second order hyperpolarizabilities, since this method is better suited for large molecules. Corrections for dynamic fields and bulk effects will be discussed in detail, focusing on solvent effects, conformational isomerization, core effects, dispersion, and hydrogen bonding. Several results will be compared with data obtained from third-harmonic-generation (THG) and dc-induced second harmonic generation (EFISH) measurements. These comparisons will demonstrate the qualitative ability of the method to predict the relative strengths of hyperpolarizabilities of a class of compounds. The future application of molecular mechanics, as well as other techniques, in the study of bulk properties and solid state defects will be addressed. The relationship between large values for nonlinear optical properties and large conjugation lengths is well known, and is particularly important for third-order processes. For this reason, the materials with the largest observed nonresonant third-order properties are conjugated polymers. An example of this type of polymer is polydiacetylene. One of the problems in dealing with polydiacetylene is that substituents which may enhance its nonlinear properties may ultimately prevent it from polymerizing. A model which attempts to predict the likelihood of solid-state polymerization is considered, along with the implications of the assumptions that are used. Calculations of the third-order optical properties and their relationship to first-order properties and energy gaps will be discussed. The relationship between monomeric and polymeric third-order optical properties will also be considered. Author

TEMPERATURE DEPENDENCE OF PROTEIN SOLUBILITY-DETERMINATION, APPLICATION TO CRYSTALLIZATION, AND GROWTH KINETICS STUDIES Abstract Only c76

Franz Rosenberger *In* NASA. Marshall Space Flight Center, Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 47 (For primary document see N94-24338 06-23)

Avail: CASI HC A01/MF A03

A scintillation method was developed for determinations of the temperature dependence of the solubility, and of nucleation induction times of proteins, in 50-100 mu(l) volumes of solution. Solubility data for lysozyme and horse serum albumin were obtained for various combinations of pH and precipitant concentrations. These data and the nucleation induction information were used for dynamic crystallization control, that is, for the controlled separation of nucleation and growth stages. Individual lysozyme and horse serum albumin crystals were grown in 15-20 mu(l) solution volumes contained in x-ray capillaries. The morphology and kinetics of the growth and dissolution of lysozyme in aqueous solutions with 2.5 percent NaCl and at pH = 4.5 was studied in situ with a depth resolution of 300 A (4 unit cells) by high resolution optical microscopy and digital image processing. The bulk super- or under saturation, sigma, of the solution inside a closed growth cell was controlled by temperature. The growth habit was bound by (110) and (101) faces that grew through layer spreading, although with different growth rate dependencies on supersaturation/temperature. At sigma less than 10 (obtained at higher temperatures) growth was purely kinetic ally controlled, with impurity effects (macrostep formation and kinetic hindrance) becoming significant for sigma less than 2. At sigma greater than 10 (lower temperatures), anisotropies in the interfacial kinetics were more pronounced, with interfacial kinetics and bulk transport becoming equally important to the growth morphology. Growth rates were growth history dependent. The formation of striations (layers of irregularly incorporated solution) was unambiguously correlated with growth temperature variations. Etching exposed dislocations and various high-index faces whose growth morphologies were studied during return to the steady state growth form. Growth steps were observed to originate from two-dimensional nuclei or from outcrops of growth striations, and from dislocations that preferentially formed in growth sector boundaries. Author

MODELING OF PCG FLUID DYNAMICS: SALIENT RESULTS c29

N. Ramachandran *In its* Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 49-60 (For primary document see N94-24338 06-23)

Avail: CASI HC A03/MF A03

Materials processing in space-based laboratories has already yielded higher quality crystals during previous space flights, and opportunities for several fluids experiments are anticipated during the extended duration missions planned for the future. Crystal growth in space benefits not only from its reduced gravity environment but also from the absence of the hydrostatic pressure which assists certain crystal growth and refinement methods. Gravity-driven phenomena are thus reduced in strength, and a purely diffusive fluid's behavior can be attained. In addition, past materials science experiments have shown that microgravity can also help produce larger crystals. While gravity-related effects are definitely curtailed in space, they are nevertheless present to some degree due to the acceleration environment onboard the spacecraft. This residual acceleration level is comprised of quasi-steady, oscillatory, and transient components, and is caused by a variety of mechanisms. For example, gravity gradient forces produce low frequency disturbances, and the operation of machinery, control thrusters, solar panels, human activity, etc. contribute to higher frequency accelerations. These disturbances are collectively referred to as g-jitter, and they can be deleterious to certain experiments where the minimization of the acceleration level is important. Advanced vibration isolation techniques can be utilized to actively filter out some of the detrimental frequencies and help in obtaining optimum results. However, the successful application of this technology requires the detailed analysis of candidate fluids experiments to gauge their response to g-jitter and to determine their acceleration sensitivities. Several crystal growth experiments in the Protein Crystal Growth (PCG) area, besides others, are expected to be carried out on future shuttle flights and on Space Station Freedom. The need for vibration isolation systems or components for microgravity science experiments can be expected to grow as experiments and available hardware becomes more complex. This technology will also find increased application as the science community develops an awareness of their specific needs relative to the environment available in manned space missions. Vibration isolation research strives to develop a microgravity environment requirement that defines tolerance limits on the allowable g-level, and provides the required technology to achieve it. This effort will assist in establishing the tolerable acceleration levels for specific fluids experiments. The primary effort is directed towards modeling PCG and the approach undertaken for this investigation is outlined. The objectives of this research are: (1) to computationally determine vibration sensitivity of protein crystal growth experiments; (2) determine if these experiments can benefit from vibration isolation techniques; and (3) provide realistic requirements for vibration isolation technology. LOW-GRAVITY ELECTRODEPOSITION AND GROWTH OF POLYMER THIN FILMS WITH LARGE THIRD-ORDER OPTICAL NONLINEARITIES BY ELECTROCHEMICAL PROCESSES FOR DEVICES: THIOPHENE-BASED POLYMERS Abstract Only c29

Benjamin G. Penn and Clyde Riley (Alabama Univ., Huntsville.) *In its* Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 61-62 (For primary document see N94-24338 06-23)
Avail: CASI HC A01/MF A03

It has been proposed that NLO thin film properties may be improved by low-gravity processing. Strong candidates for NLO thin film applications are the polythiophenes. Polymeric thiophenes are attractive materials due to their ease of preparation, stability, and high X(exp 3). A simple and convenient method for preparation of polythiophenes is electrochemical oxidation. We will apply some of our experience and lessons learned in low-gravity metal, metal/cermet electrode position to improve the quality of polythiophene(s) thin films. In low gravity electrode position of Ni at a high rate on an Au substrate often results in the production of an x-ray non diffracting surface. Cobalt metal deposition does not give this result nor does Ni when deposited similarly on a glassy carbon substrate. Co/Ni alloy composition produced during electrode position is strongly dependent upon the amount of convection. Code position of neutral inert cermets with metals is influenced significantly by the presence of gravity and the size of the cermets. Tracks left in the 1-g surfaces by unsuccessful particle occlusion indicate suspension of the large particles is not the only reason for poor volume percentages of the larger particles in the deposits. All size particles are more homogeneously distributed in the deposits in low-gravity electrocodeposition than in 1-g. Low gravity gives larger volume percentages for the larger particles in the deposits, while 1-g gives larger volume percentages for the smaller particles. Intermediate size particles give mixed results. The experimental cells were constructed with flat electrode end plates such that 1-g bench reference electrode positions could be carried out at various orientations with respect to gravity. A series of bench studies using similar designed cells are suggested so that convection modification can be applied to electrochemical thin film preparation. Convection effects can then be coupled with other parameter variations in current, temperature, concentration, solvent, electrolyte, and anode substrates to optimize the properties of NLO thin films before resorting to low-gravity processing. POLYDIACETYLENE THIN FILMS FOR NONLINEAR OPTICAL APPLICATIONS Abstract Only c74

Mark S. Paley *In its* Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 63-64 (For primary document see N94-24338 06-23)
Avail: CASI HC A01/MF A03

One very promising class of organic compounds for nonlinear optical (NLO) applications are polydiacetylenes, which are novel in that they are highly conjugated polymers which can also be crystalline. Polydiacetylenes offer several advantages over other organic materials: because of their highly conjugated electronic structures, they are capable of possessing large optical nonlinearities with fast response times; because they are crystalline, they can be highly ordered, which is essential for optimizing their NLO properties; and, last, because they are polymeric, they can be formed as thin films, which are useful for device fabrication. We have actively been carrying out ground-based research on several compounds of interest. Derived from text

CRYSTAL GROWTH OF ORGANICS FOR NONLINEAR OPTICAL APPLICATIONS c74

N. B. Singh and R. Mazelsky *In* NASA. Marshall Space Flight Center, Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 65-66 (For primary document see N94-24338 06-23)
Avail: CASI HC A01/MF A03

The crystal growth and characterization of organic and inorganic nonlinear optical materials were extensively studied. For example, inorganic crystals such as thallium arsenic selenide were studied in our laboratory for several years and crystals in sizes over 2.5 cm in diameter are available. Organic crystals are suitable for the ultraviolet and near infrared region, but are relatively less developed than their inorganic counterparts. Very high values of the second harmonic conversion efficiency and the electro-optic coefficient were reported for organic compounds. Single crystals of a binary organic alloy based on m.NA and CNA were grown and higher second harmonic conversion efficiency than the values reported for m.NA were observed. Author (revised)

A focused approach to development and evaluation of organic polymer films for use in optoelectronics is presented. The issues and challenges that are addressed include: (1) material synthesis, purification, and the tailoring of the material properties; (2) deposition of uniform thin films by a variety of methods; (3) characterization of material physical properties (thermal, electrical, optical, and electro-optical); and (4) device fabrication and testing. Photonic materials, devices, and systems were identified as critical technology areas by the Department of Commerce and the Department of Defense. This approach offers strong integration of basic material issues through engineering applications by the development of materials that can be exploited as the active unit in a variety of polymeric thin film devices. Improved materials were developed with unprecedented purity and stability. The absorptive properties can be tailored and controlled to provide significant improvement in propagation losses and nonlinear performance. Furthermore, the materials were incorporated into polymers that are highly compatible with fabrication and patterning processes for integrated optical devices and circuits. By simultaneously addressing the issues of materials development and characterization, keeping device design and fabrication in mind, many obstacles were overcome for implementation of these polymeric materials and devices into systems. We intend to considerably improve the upper use temperature, poling stability, and compatibility with silicon based devices. The principal device application that was targeted is a linear electro-optic modulation etalon. Organic polymers need to be properly designed and coupled with existing integrated circuit technology to create new photonic devices for optical communication, image processing, other laser applications such as harmonic generation, and eventually optical computing. The progression from microscopic sample to a suitable film-forming material in a working device is a complex, multifaceted endeavor. It requires close attention to maintaining the optical properties of the electro-optic active portion of the polymer while manipulating the polymer structure to obtain the desired secondary polymer properties. FEASIBILITY STUDY: MONODISPERSE POLYMER PARTICLES CONTAINING LASER-EXCITABLE DYES c27

John W. Vanderhoff and Jing-Hong Chen *In* NASA. Marshall Space Flight Center, Microgravity Studies of Organic and Polymeric Materials Dec. 1993 p 69-88 (For primary document see N94-24338 06-23)
Avail: CASI HC A03/MF A03

The objective was to determine the feasibility of the preparation of monodisperse spherical poly(methyl methacrylate) and polystyrene particles that contain laser-excitable dyes in the size range 0.1 microns to 1 cm. Poly(methyl methacrylate) and polystyrene were chosen because of their excellent optical properties. The sphericity was required for uniformity of spectral output of re-irradiated light from the dye-containing particles. The monodispersity was required to give each particle the same optical properties when exposed to laser light. Author (revised)

Our research group has been interested in the processing-structure-property relationships in semicrystalline polymers and blends for many years. In situ real time x ray scattering at elevated temperatures is being used to monitor the development of structure. An ongoing collaboration with Dr. Malcolm Capel at the Brookhaven National Synchrotron Light Source allows the performance of real time wide and small angle x ray scattering to study the phase transformations in semicrystalline polymers. The first part of my presentation will be about our recent use of x ray scattering to study blends of poly(ethylene terephthalate) with polyarylates. The purpose of the next portion of the presentation is to show how we may study effects of self-deformation of polymers during processing in the gravity environment, using real time x ray scattering. In this way, how processing stresses alter the microstructure of semicrystalline polymers was learned, and ultimately microgravity processing strategies that will result in more uniform morphology in these polymers is hoped to be developed. An autocatalytic reaction in an unstirred vessel can support a constant velocity wavefront resulting from the coupling of diffusion to the chemical reaction. A flare front is a common example in which heat is the autocatalytic species that diffuses into unreacted regions stimulating a reaction that produces more heat. Traveling fronts were studied in synthetic polymerization reactions under high pressure by workers in the former USSR. More recently, propagating fronts of methacrylic acid polymerization were studied under ambient conditions, both with video techniques and by NMR. Author (revised)

All polymeric materials in their final application are aggregates of many molecules. For linear macromolecules, these aggregates are highly entangled and their macroscopic properties are affected in a little-known way by the interpenetration and entanglements of the molecules. Over the years, we have done occasional investigations of single molecule single crystals and found that there are many unsolved questions about their nucleation, growth, kinetically determined shape, and ultimate path to equilibrium morphology on annealing. This initial work could be extended by a study of the applicability of microgravity methods for the production and study of the formation of single molecule particles. The production of separated molecules of sufficient size to produce phase-like behavior would involve perhaps a spray of solutions containing single molecules, followed by evaporation of the volatiles, or precipitation out of dispersion droplets. Other methods may involve Langmuir films etc., as shown in our prior work. The microgravity environment should enhance the efficiency of any of these methods by avoiding the joining of growing particles by reduction of convection and settling due to density differences. Once produced, the single molecule droplets are to be quenched into the glassy state and analyzed morphologically and thermally. Their shape alone can be used for molecular mass determination (an old problem that suffered from the need to estimate the shape of collapsed (flat) droplets on a surface). Next would be the study of changes of properties as a function of time, temperature, and molecular mass (and distribution) on fusion to macroscopic single phases. Author (revised)

Nonlinear optical materials (NLO) can be used to extend the useful frequency range of lasers. Frequency generation is important for laser-based remote sensing and optical data storage. Another NLO effect, the electro-optic effect, can be used to modulate the amplitude, phase, or polarization state of an optical beam. Applications of this effect in telecommunications and in integrated optics include the impression of information on an optical carrier signal or routing of optical signals between fiber optic channels. In order to utilize these effects most effectively, it is necessary to synthesize materials which respond to applied fields very efficiently. In this talk, it will be shown how the development of a fundamental understanding of the science of nonlinear optics can lead to a rational approach to organic molecules and materials with optimized properties. In some cases, figures of merit for newly developed materials are more than an order of magnitude higher than those of currently employed materials. Some of these materials are being examined for phased-array radar and other electro-optic switching applications. Author (revised)

ON THE MECHANISM OF ACTION OF 3',5'-CYCLIC ADENOSINE MONOPHOSPHATE: A STUDY OF FOUR- AND FIVE-COORDINATED PHOSPHORUS COMPOUNDS, MODELLING THE ACTIVATED STATE OF cAMP Ph.D. Thesis
Nicolaas Lambertus H Broeders 1993 132 p
(ISBN-9-03-860222-7; ETN-94-95324) Avail: CASI HC A07/MF A02

A study to gain insight into the interaction of cyclic adenosine monophosphate (cAMP) with enzymes, like protein kinases and phosphodiesterases, is reported. The role of phosphorus in cAMP during its interaction with enzymes was concentrated upon. Five coordinated phosphorus model systems, with a Trigonal bipyramidal geometry (TBP), which are supposed to be intermediates formed during the interaction between cAMP and enzymes, like protein kinases and phosphodiesterases, were studied. During this process the coordination of phosphorus increases from four, P(sup 4), to five, P(sup 5). This phosphorus coordination enhancing process and the resulting structural properties of the intermediates are studied. A set of stable P(sup 5) model systems, simulating the interaction between cAMP and an enzyme (protein kinase, phosphodiesterase, or CAP-dimer), which are studied by H-1 NMR (nuclear magnetic resonance) spectroscopy, is dealt with. A P-31 NMR study on the alkaline hydrolysis of a set of O-18 labelled cis nucleotide 3',5' cyclic aryl monophosphates is presented. A cAMP model compound, that is 2'-O-methyl-cis adenosine 3',5' cyclic monophosphate, is dealt with. ESA

It is considered that the toughness across the grain of carbon fiber composites can be improved by reducing the cure shrinkage of the matrix. In an experimental investigation, the expanding monomer dinorbornene spiro ortho carbonate (DNSOC) was added to the epoxy in an attempt to reduce shrinkage stress. In addition, a two stage curing process was used to ensure that the expanding monomer did not polymerize while the resin mixture was still liquid. A reduction in shrinkage stress was observed, accompanied by a reduction in the glass transition temperature. Bi-material strip tests and thermal expansion measurements showed that there was very little chemical shrinkage stress in the copolymer system. Stress relaxation measurements showed that the stress generated by the chemical expansion of the DNSOC disappeared quickly during the cure. It was thus concluded that the shrinkage pressure was not significantly affected by the expansion of the DNSOC. Rather, the reduction of the overall shrinkage was due entirely to the reduction of the glass transition temperature. The toughness of the composites remained unchanged. Author (CISTI)

OPTIMIZATION OF LAMINATE ORIENTATION TO ENHANCE FAILURE PROPERTIES M.S. Thesis

Hui Hongwei 1993 94 p

(ISBN-0-315-83539-7; CTN-94-60947) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The APC-2 polyether ether ketone/carbon fiber composite laminate was studied in both static and fatigue tests. Laminate theory and static tests were employed to study the maximum failure stress. The load applied was uniaxial and its orientation started from 0 deg fiber direction. Laminate theory and experimental results show that as the load direction changes, the failure stress will change and reach a maximum at 22.5 deg and 67.5 deg. Theoretical maximum failure stress values at these angles are 20 percent higher than those at 0, 45, or 90 deg; static test results give values 10 percent higher, both in tension and compression. The finite element method was used to reveal the stress field in the laminate. As the load direction changed, both the stress pattern and failure modes changed. Fatigue results are consistent with static results. The quasi-isotropic laminate has the same in-plane mechanical properties when intact, but once first failure occurs, these properties change. This change manifests itself in both the maximum failure stress and fatigue properties. Current studies show that under uniaxial load, the best performance is at angles of 22.5 deg and 67.5 deg. Refractory intermetallic silicides are receiving increasing consideration for use as high temperature structural materials. A5Si3 compositions are particularly interesting due to their ability to incorporate a variety of interstitial ternary additions. These ternary additions present a unique opportunity to potentially tailor physical properties. Previous experimental work has shown that these additions can decrease the inherent thermal expansion anisotropy of Ti5Si3. This paper reviews some of the literature with respect to binary and ternary silicides of the form A5Si3Z(x). Recent experimental work by the authors on two promising compositions, Ti5Si3 and Mo5Si3, is discussed. Interstitial additions substantially improve the isothermal oxidation resistance of both Ti5Si3 and Mo5Si3. The lattice parameter of Ti5Si3 is significantly changed by ternary interstitial additions, indicating the extensive solubility of Ti5Si3 for such additions. The level of similar additions affects the phase assemblage of Mo5Si3. Hardness and toughness values from indentation measurements for selected compositions are given. DOE

CREEP DEFORMATION CHARACTERISTICS OF DUCTILE DISCONTINUOUS FIBER REINFORCED COMPOSITES

S. B. Biner 1993 14 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials in Conjunction With Materials Week and the Materials Applications and Services Exposition, Pittsburgh, PA, 17-21 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print

(Contract W-7405-eng-82)

(DE94-000697; IS-M-768; CONF-931009-4) Avail: Issuing Activity (Department of Energy (DOE))

Role of material parameters and geometric parameters of ductile reinforcing phase on the creep deformation behavior of 20% discontinuously reinforced composite was numerically investigated including debonding and pull-out mechanisms. Results indicate that for rigidly bonded interfaces, the creep rate of the composite is not significantly influenced by the material properties and geometric parameters of the ductile reinforcing phase due to development of large hydrostatic stress and constrained deformation in the reinforcement. For debonding interfaces, the geometric parameters of the reinforcing phase are important; however, even with very weak interfacial behavior low composite creep rates can be achieved by suitable selection of the geometric parameters of the ductile reinforcing phase. DEVELOPMENT OF SILICON NITRIDE COMPOSITES WITH CONTINUOUS FIBER REINFORCEMENT

T. L. Starr (Georgia Inst. of Tech., Atlanta.), D. L. Mohr (Georgia Inst. of Tech., Atlanta.), W. J. Lackey (Georgia Inst. of Tech., Atlanta.), and J. A. Hanigofsky (Georgia Inst. of Tech., Atlanta.) Oct. 1993 25 p

(Contract DE-AC05-84OR-21400)

(DE94-001996; ORNL/Sub-87-00184/04) Avail: CASI HC A03/MF A01

The composites were fabricated using ultrafine Si powders prepared by attritor milling; the powders exhibit full conversion to Si nitride in less than 3 h at less than 1200 C (these conditions reduce degradation of the fibers compared to conventional). Effects of processing conditions on fiber properties and the use of fiber coatings to improve stability during processing as well as change the fiber-matrix interfacial properties were investigated. A duplex carbon-silicon carbide coating, deposited by CVD, reduced fiber degradation in processing, and it modified the fiber-matrix adhesion. Si nitride matrix composites were fabricated using reaction sintering, forming laminates, filament-wound plates, and tubes. In each case, an attritor milled Si powder slurry is infiltrated into ceramic fiber preforms or tows, which are then assembled to form a 3-D structure for reaction sintering. The resulting composites have properties comparable to chemical vapor infiltration densified composites, with reasonable strengths and graceful composite fracture behavior. DOE

(ISAL-93-0027; ETN-94-95170) Avail: CASI HC A07/MF A02

The interfacial micromechanical study of glass/epoxy model composites was carried out by tearing, by fragmentation and by microindentation experiments. The purpose was to study the effect of the fiber's surface silane content on the fiber's charge transfer and test relationships. The interfacial characteristics are known to influence the mechanical behavior of a composite material. The fragmentation tests demonstrated that the fragmentation phenomena is not well known and that simplifying hypothesis induces wrong test evaluations. The matrix local behavior was highlighted. The effect of lubrication on the elementary damage and the effect of the indentator characteristics on the decoherence force were demonstrated. The complexity of the elementary damage was stressed. FATIGUE LIFE AND CRACK GROWTH PREDICTION METHODOLOGY

J. C. Newman, Jr., E. P. Phillips, and R. A. Everett, Jr. (Army Vehicle Structures Lab., Hampton, VA.) Oct. 1993 47 p Presented at the AGARD Structures and Materials Panel Workshop on an Assessment of Fatigue Damage and Crack Growth Prediction Techniques, Bordeaux, France, 29-30 Sep. 1993
(RTOP 538-02-10-01)
(NASA-TM-109044; NAS 1.15:109044) Avail: CASI HC A03/MF A01

The capabilities of a plasticity-induced crack-closure model and life-prediction code to predict fatigue crack growth and fatigue lives of metallic materials are reviewed. Crack-tip constraint factors, to account for three-dimensional effects, were selected to correlate large-crack growth rate data as a function of the effective-stress-intensity factor range (delta(K(sub eff))) under constant-amplitude loading. Some modifications to the delta(K(sub eff))-rate relations were needed in the near threshold regime to fit small-crack growth rate behavior and endurance limits. The model was then used to calculate small- and large-crack growth rates, and in some cases total fatigue lives, for several aluminum and titanium alloys under constant-amplitude, variable-amplitude, and spectrum loading. Fatigue lives were calculated using the crack growth relations and microstructural features like those that initiated cracks. Results from the tests and analyses agreed well. Author (revised)

TIME DEPENDENT BEHAVIOR OF A GRAPHITE/THERMOPLASTIC COMPOSITE AND THE EFFECTS OF STRESS AND PHYSICAL AGING

Thomas S. Gates and Mark Feldman (Old Dominion Univ., Norfolk, VA.) Nov. 1993 41 p Presented at the AIAA/ASME/ASCE/AHS/ASC 34th SDM Conference, La Jolla, CA, 19-21 Apr. 1993
(RTOP 505-63-50-04)
(NASA-TM-109047; NAS 1.15:109047) Avail: CASI HC A03/MF A01

Two complimentary studies were performed to determine the effects of stress and physical aging on the matrix dominated time dependent properties of IM7/8320 composite. The first of these studies, experimental in nature, used isothermal tensile creep/aging test techniques developed for polymers and adapted them for testing of the composite material. From these tests, the time dependent transverse (S22) and shear (S66) compliance's for an orthotropic plate were found from short term creep compliance measurements at constant, sub-T(sub g) temperatures. These compliance terms were shown to be affected by physical aging. Aging time shift factors and shift rates were found to be a function of temperature and applied stress. The second part of the study relied upon isothermal uniaxial tension tests of IM7/8320 to determine the effects of physical aging on the nonlinear material behavior at elevated temperature. An elastic/viscoplastic constitutive model was used to quantify the effects of aging on the rate-independent plastic and rate-dependent viscoplastic response. Sensitivity of the material constants required by the model to aging time were determined for aging times up to 65 hours. Verification of the analytical model indicated that the effects of prior aging on the nonlinear stress/strain/time data of matrix dominated laminates can be predicted. Author

MECHANICAL AND THERMAL BUCKLING ANALYSIS OF SANDWICH PANELS UNDER DIFFERENT EDGE CONDITIONS

William L. Ko Washington Oct. 1993 14 p Presented at the Pacific International Conference on Aerospace Science and Technology PICAST'1, Taiwan, Republic of China, 6-9 Dec. 1993
(RTOP 505-63-40)
(NASA-TM-4535; H-1953; NAS 1.15:4535) Avail: CASI HC A03/MF A01

By using the Rayleigh-Ritz method of minimizing the total potential energy of a structural system, combined load (mechanical or thermal load) buckling equations are established for orthotropic rectangular sandwich panels supported under four different edge conditions. Two-dimensional buckling interaction curves and three dimensional buckling interaction surfaces are constructed for high-temperature honeycomb-core sandwich panels supported under four different edge conditions. The interaction surfaces provide easy comparison of the panel buckling strengths and the domains of symmetrical and antisymmetrical buckling associated with the different edge conditions. Thermal buckling curves of the sandwich panels also are presented. The thermal buckling conditions for the cases with and without thermal moments were found to be identical for the small deformation theory. In sandwich panels, the effect of transverse shear is quite large, and by neglecting the transverse shear effect, the buckling loads could be overpredicted considerably. Clamping of the edges could greatly increase buckling strength more in compression than in shear. Author (revised)

OUT OF PLANE GRADIENTS IN LAMINATED COMPOSITES Final Report, 17 Dec. 1987 - 31 Dec. 1993

Carl T. Herakovich 20 Jan. 1994 3 p
(Grant NAG1-841)
(NASA-CR-194875; NAS 1.26:194875) Avail: CASI HC A01/MF A01

The research under this grant focused on three different, but related, research projects. All three projects were concerned with predicting the interlaminar stresses that develop in laminated composites in the presence of free edges. The first project was dedicated to the development of a new semi-analytical approximate solution for predicting interlaminar stresses. The second project was devoted to a study of the influence of boundary conditions, geometric parameters, and material modelling on interlaminar stresses in stiffened composite panels. The third project was dedicated to the development of a new finite element for efficient analysis of interlaminar stresses in curved, stiffened panels. A summary of each of the projects is given. ANALYSIS OF LOCAL DELAMINATIONS CAUSED BY ANGLE PLY MATRIX CRACKS

Satish A. Salpekar (Analytical Services and Materials, Inc., Hampton, VA.), T. Kevin OBrien (Army Vehicle Structures Lab., Hampton, VA.), and K. N. Shivakumar (North Carolina Agricultural and Technical State Univ., Greensboro.) Nov. 1993 67 p
(RTOP 538-02-10-01)
(NASA-TM-109052; NAS 1.15:109052) Avail: CASI HC A04/MF A01

Two different families of graphite/epoxy laminates with similar layups but different stacking sequences, (0,theta,-theta) sub s and (-theta/theta/0) sub s were analyzed using three-dimensional finite element analysis for theta = 15 and 30 degrees. Delaminations were modeled in the -theta/theta interface, bounded by a matrix crack and the stress free edge. The total strain energy release rate, G, along the delamination front was computed using three different techniques: the virtual crack closure technique (VCCT), the equivalent domain Integral (EDI) technique, and a global energy balance technique. The opening fracture mode component of the strain energy release rate, GI, along the delamination front was also computed for various delamination lengths using VCCT. The effect of residual thermal and moisture stresses on G was evaluated. Author (revised)

A PREDICTION METHOD FOR THE COMPRESSIVE STRENGTH OF IMPACT DAMAGED COMPOSITE LAMINATES

Y. Xiong, C. Poon, P. V. Straznicky (Carleton Univ., Ottawa, Ontario.), and H. Vietinghoff (Carleton Univ., Ottawa, Ontario.) Sep. 1993 23 p
(CTN-94-60925) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

An analytical method for the prediction of the compressive strength of composite laminates containing impact damage has been developed. Using the characteristics of the impact damage detected by the ultrasonic time-of-flight C-scan technique, the state of the damage is modeled by an elliptical soft inclusion. The degradation of the elastic moduli of the material in the inclusion is determined by a sublaminate buckling analysis. The stress distribution in the laminate containing the inclusion with the reduced moduli is determined using a complex potential method and the stress results are used in conjunction with three failure criteria to predict the residual compressive strength. Compression after impact tests on flat laminates manufactured from the Toray T800H/3900-2 material have been conducted to produce experimental results for validating the analytical method. Good agreements between predicted residual compressive strengths and experimental results have been obtained. Author (CISTI)

HUMIDITY EFFECTS ON SOLUBLE CORE MECHANICAL AND THERMAL PROPERTIES (POLYVINYL ALCOHOL/MICROBALLOON COMPOSITE) TYPE CG EXTENDOSPHERES, VOLUME 2 Final Report

28 May 1993 314 p
(Contract NAS8-37800)
(NASA-CR-193893; NAS 1.26:193893; EMTL-Rept-1539; FMI-EMTL-W/A-3111) Avail: CASI HC A14/MF A03

This document constitutes the final report for the study of humidity effects and loading rate on soluble core (PVA/MB composite material) mechanical and thermal properties under Contract No. 100345. This report describes test results procedures employed, and any unusual occurrences or specific observations associated with this test program. The primary objective of this work was to determine if cured soluble core filler material regains its tensile and compressive strength after exposure to high humidity conditions and following a drying cycle. Secondary objectives include measurements of tensile and compressive modulus, and Poisson's ratio, and coefficient of thermal expansion (CTE) for various moisture exposure states. A third objective was to compare the mechanical and thermal properties of the composite using 'SG' and 'CG' type extendospheres. The proposed facility for the manufacture of soluble cores at the Yellow Creek site incorporates no capability for the control of humidity. Recent physical property tests performed with the soluble core filler material showed that prolonged exposure to high humidity significantly degradates in strength. The purpose of these tests is to determine if the product, process or facility designs require modification to avoid imparting a high risk condition to the ASRM. Derived from text

STRUCTURAL DESIGN CRITERIA FOR FILAMENT-WOUND COMPOSITE SHELLS Final Report

H. T. Hahn, D. W. Jensen, S. J. Claus, S. P. Pai, and P. A. Hipp Jan. 1994 172 p
(Grant NAG1-982)
(NASA-CR-195125; NAS 1.26:195125) Avail: CASI HC A08/MF A02

Advanced composite cylinders, manufactured by filament winding, provide a cost effective solution to many present structural applications; however, the compressive performance of filament-wound cylinders is lower than comparable shells fabricated from unidirectional tape. The objective of this study was to determine the cause of this reduction in thin filament-wound cylinders by relating the manufacturing procedures to the quality of the cylinder and to its compressive performance. The experiments on cylinder buckling were complemented by eigenvalue buckling analysis using a detailed geometric model in a finite element analysis. The applicability of classical buckling analyses was also investigated as a design tool. Derived from text

HIGH STRAIN RATE SUPERPLASTICITY IN METALS AND COMPOSITES

T. G. Nieh, J. Wadsworth, and K. Higashi (Osaka Prefecture Univ., Sakai, Japan.) Jul. 1993 8 p Presented at the International Union of Materials Research Societies on Advanced Materials, Tokyo, Japan, 31 Aug. - 4 Sep. 1993
(Contract W-7405-eng-48)
(DE94-001521; UCRL-JC-114187; CONF-9308122-13) Avail: CASI HC A02/MF A01

Superplastic behavior at very high strain rates (at or above 1 s(exp -1)) in metallic-based materials is an area of increasing interest. The phenomenon has been observed quite extensively in metal alloys, metal-matrix composites (MMC), and mechanically-alloyed (MA) materials. In the present paper, experimental results on high strain rate behavior in 2124 Al-based materials, including Zr-modified 2124, SiC-reinforced 2124, MA 2124, and MA 2124 MMC, are presented. Except for the required fine grain size, details of the structural requirements of this phenomenon are not yet understood. Despite this, a systematic approach to produce high strain rate superplasticity (HSRS) in metallic materials is given in this paper. Evidences indicate that the presence of a liquid phase, or a low melting point region, at boundary interfaces is responsible for HSRS. DOE

PREDICTION OF THERMAL CYCLING INDUCED CRACKING IN POLMER MATRIX COMPOSITES Semiannual Report, Aug. 1993 - Jan. 1994

Hugh L. McManus Feb. 1994 162 p
(Grant NAG1-1493)
(NASA-CR-195135; NAS 1.26:195135) Avail: CASI HC A08/MF A02

The work done in the period August 1993 through February 1994 on the 'Prediction of Thermal Cycling Induced Cracking In Polymer Matrix Composites' program is summarized. Most of the work performed in this period, as well as the previous one, is described in detail in the attached Master's thesis, 'Analysis of Thermally Induced Damage in Composite Space Structures,' by Cecelia Hyun Seon Park. Work on a small thermal cycling and aging chamber was concluded in this period. The chamber was extensively tested and calibrated. Temperatures can be controlled very precisely, and are very uniform in the test chamber. Based on results obtained in the previous period of this program, further experimental progressive cracking studies were carried out. The laminates tested were selected to clarify the differences between the behaviors of thick and thin ply layers, and to explore other variables such as stacking sequence and scaling effects. Most specimens tested were made available from existing stock at Langley Research Center. One laminate type had to be constructed from available prepreg material at Langley Research Center. Specimens from this laminate were cut and prepared at MIT. Thermal conditioning was carried out at Langley Research Center, and at the newly constructed MIT facility. Specimens were examined by edge inspection and by crack configuration studies, in which specimens were sanded down in order to examine the distribution of cracks within the specimens. A method for predicting matrix cracking due to decreasing temperatures and/or thermal cycling in all plies of an arbitrary laminate was implemented as a computer code. The code also predicts changes in properties due to the cracking. Extensive correlations between test results and code predictions were carried out. The computer code was documented and is ready for distribution. Author (revised)

CRASHWORTHINESS ANALYSIS USING ADVANCED MATERIAL MODELS IN DYNA3D

R. W. Logan, M. J. Burger, L. D. McMichael, and R. D. Parkinson (Kaiser Aluminum and Chemical Corp., Pleasanton, CA.) 22 Oct. 1993 12 p Presented at the Annual Winter Meeting of the American Society of

Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993
(Contract W-7405-eng-48)
(DE94-002988; UCRL-JC-114579; CONF-931121-30) Avail: CASI HC A03/MF A01

As part of an electric vehicle consortium, LLNL and Kaiser Aluminum are conducting experimental and numerical studies on crashworthy aluminum spaceframe designs. They have jointly explored the effect of heat treat on crush behavior and duplicated the experimental behavior with finite-element simulations. The major technical contributions to the state of the art in numerical simulation arise from the development and use of advanced material model descriptions for LLNL's DYNA3D code. Constitutive model enhancements in both flow and failure have been employed for conventional materials such as low-carbon steels, and also for lighter weight materials such as aluminum and fiber composites being considered for future vehicles. The constitutive model enhancements are developed as extensions from LLNL's work in anisotropic flow and multiaxial failure modeling. Analysis quality as a function of level of simplification of material behavior and mesh is explored, as well as the penalty in computation cost that must be paid for using more complex models and meshes. The lightweight material modeling technology is being used at the vehicle component level to explore the safety implications of small neighborhood electric vehicles manufactured almost exclusively from these materials. MATRIX FATIGUE CRACKING MECHANISMS OF ALPHA(2) TMC FOR HYPERSONIC APPLICATIONS
Timothy P. Gabb and John Gayda Feb. 1994 29 p Proposed for presentation at the Life Prediction Methodology for Titanium Matrix Composites, Hilton Head, SC, 22-24 Mar. 1994; sponsored by the American Society for Testing and Materials
(RTOP 505-63-1A)
(NASA-TM-106506; E-8610; NAS 1.15:106506) Avail: CASI HC A03/MF A01

The objective of this work was to understand matrix cracking mechanisms in a unidirectional alpha(sub 2) TMC in possible hypersonic applications. A (0)(sub 8) SCS-6/Ti-24Al-11Nb (at. percent) TMC was first subjected to a variety of simple isothermal and nonisothermal fatigue cycles to evaluate the damage mechanisms in simple conditions. A modified ascent mission cycle test was then performed to evaluate the combined effects of loading modes. This cycle mixes mechanical cycling at 150 and 483 C, sustained loads, and a slow thermal cycle to 815 C. At low cyclic stresses and strains more common in hypersonic applications, environment-assisted surface cracking limited fatigue resistance. This damage mechanism was most acute for out-of-phase nonisothermal cycles having extended cycle periods and the ascent mission cycle. A simple linear fraction damage model was employed to help understand this damage mechanism. Time-dependent environmental damage was found to strongly influence out-of-phase and mission life, with mechanical cycling damage due to the combination of external loading and CTE mismatch stresses playing a smaller role. The mechanical cycling and sustained loads in the mission cycle also had a smaller role. Author (revised)

Research on the analysis of brittle tendons and fibers in a cement based matrix is presented. The aim is to find simple and reliable design assumptions when developing and studying structural ideas. Composite tendons are similar to the normal prestressing tendons, but they are soft and brittle. Ductility can be achieved by increasing the amount of tendons so that the tendons do not break, but rather that there are plastic deformations in the compression zone instead. The strength of fiber reinforced concrete can be estimated by the classical law of mixture method. Fiber concrete can be used as shear reinforcement and in thin structures without main reinforcement. A difficult task is to determine the bond strength between the matrix and fiber and the stress-strain relationship of a composite. The calculation methods presented give conservative results when compared to the test results. However, there is no additional benefit in strength or in material costs. The main interest concerns durability and ease of production. ESA

COMPOSITES AND TEXTILE REINFORCEMENT [KOMPOSIITIT JA TEKSTIILILUJITE]
Mikael Epstein, Esa Suokas, Salme Nurmi, and Mikko Karttunen Dec. 1992 176 p In FINNISH Sponsored by Technology Development Center, Finland, and Technical Research Centre of Finland, Espoo
(VTT-TIED-1424; ISBN-951-38-4318-1; ETN-94-95256) Copyright Avail: CASI HC A09/MF A02

The application of various textile processes to the reinforcement structures for composites and the properties given by the reinforcement structures to composites were investigated. The project concentrated on the development of formable, near-net-shape and pre-formed reinforcement structures as well as on the plastic composites reinforced by these reinforcements. An altered narrow fabric loom was used to fabricate T, H, and O profiles of glass yarn and roving. The critical yarn passages were investigated by yarn-tension measurements. Pultrusion products were the most interesting applications of the narrow reinforcement fabrics produced by this project. Knitting of different glass yarns into various basic main knit structures was part of the program of knitting investigation. Composites with matrices of thermoset resin were made with knitted reinforcement fabric using hand laminating and RTM (Resin Transfer Molding) techniques. The mechanical material tests with the composite materials as well as the formability tests with the knitted reinforcement fabrics indicate that knitted reinforcements apparently are suitable for easily formable reinforcements when using certain techniques with closed molds. Knitted fabrics with straight inlay yarns (glass roving) were produced in addition to the basic knitted fabrics. The laminates made with these reinforcements had properties corresponding to typical laminates made with reinforcement of unidirectional yarns. Multilayer braidings were made over mandrels to study braided reinforcement. Thereafter the braidings were impregnated with thermoset resin. Such pieces with near-set-shape braided reinforcement are probably usable, for example in the production of various pipe jointing elements. Sewing and grading techniques were used, for example in the research on the ballistic protection helmet and in the fabrication of various shaped products, for example ball valves. Textile technology can be used to produce reinforcements for composites in many different ways. By combining the possibilities offered by different methods at the product planning stage more flexible composite production methods can be developed. ESA

DISCONTINUOUS PHASE FORMATION AND SELECTIVE ATTACK OF SiC MATERIALS EXPOSED TO LOW OXYGEN PARTIAL PRESSURE ENVIRONMENTS
D. P. Butt, R. E. Tressler (Pennsylvania State Univ., University Park.), and K. E. Spear (Pennsylvania State Univ., University Park.) 1993 13 p Presented at the North Atlantic Treaty Organization (NATO) Advanced Research Workshop on Corrosion of Advanced Ceramics, Tubingen, Germany, 30 Aug. - 3 Sep. 1993
(Contract W-7405-eng-36)
(DE93-040161; LA-UR-93-3189; CONF-9308163-2) Avail: CASI HC A03/MF A01

Three SiC materials were exposed to gas mixtures containing N2, H2, and CO at 1000-1300C, 1-740 torr for a few to 1000 h. Kinetic and thermodynamic studies indicate that CO is the predominant oxidizing species. A variety of corrosion processes were observed, including surface and internal pit formation, needle growth, grain boundary attack, and attack of impurities and surrounding material. In the case of a siliconized SiC, impurities such as Ca, Al, and Fe diffused rapidly through the Si matrix forming complex calcium aluminosilicates on the surface, leaving behind internal voids. Evaluation of the mechanical properties, including fractography, revealed a variety of degradative phenomena. Efforts to identify causes of pit formation suggested that the overall process was complex. Pits formed during attack of grain boundaries and regions containing transition metal impurities. Studies of single crystals showed preferential attack near impurities and crystalline defects, indicating that damaged crystals or certain crystal orientations in the polycrystalline materials are susceptible to attack. In addition, under some conditions where pit formation was observed, the strength of certain materials increased apparently due to flaw healing. It is suggested that flaws can heal in the absence of mechanical stress due to their high surface energy. However, second phases observed within partially healed surface cracks suggest impurities also contribute to the flaw healing processes. DOE

(DE94-000895; LA-UR-93-3304; CONF-930905-10) Avail: CASI HC A03/MF A01

The measurement of equilibria by Knudsen effusion techniques and the enthalpy of formation of the actinide atoms is briefly discussed. Thermochemical data on the sublimation of the actinide fluorides is used to calculate the enthalpies of formation and entropies of the gaseous species. Estimates are made for enthalpies and entropies of the tetrafluorides and trifluorides for those systems where data is not available. The pressure of important species in the tetrafluoride sublimation processes is calculated based on this thermochemical data. DOE

REBURNING RICH-LEAN KINETICS Annual Report, 1992
P. Glarborg, K. Dam-Johansen, and P. G. Kristensen 3 Feb. 1993 19 p See also PB92-205798 Sponsored by Gas Research Inst. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract GRI-5091-260-2126)
(PB93-220887; GRI-93/0206) Avail: CASI HC A03

The objective of the work, funded by the Physical Sciences Department of GRI and Nordic Gas Technology Center, is to improve the understanding of the nitrogen chemistry at the final air addition point in reburning and to identify optimum conditions for conversion of reactive nitrogen to N2 in the region. During the past year, a parametric study of the burnout zone nitrogen chemistry has been initiated. The effect of temperature, partitioning of HCN, NO and NH3 in the flue gas, and CO concentration on the conversion of reactive nitrogen has been investigated. Results show that a temperature window exists where both HCN and NH3 act as reducing agents for NO. At the optimum temperature, significant amounts of intermediate N2O is formed. Presence of CO and other combustibles moves the temperature window towards lower temperatures. A preliminary chemical kinetic model for the nitrogen chemistry has been established to analyze the results. NTIS

CONDENSED-PHASE THERMAL DECOMPOSITION OF TATB INVESTIGATED BY ATOMIC FORCE MICROSCOPY (AFM) AND SIMULTANEOUS THERMOGRAVIMETRIC MODULATED BEAM MASS SPECTROMETRY (STMBMS)
T. A. Land, W. J. Siekhaus, M. F. Foltz, and R. Behrens, Jr. (Sandia National Labs., Livermore, CA.) May 1993 10 p Presented at the 10th Detonation Symposium, Boston, MA, 12-16 Jul. 1993
(Contract W-7405-eng-48)
(DE94-000396; UCRL-JC-114109; CONF-930713-27) Avail: CASI HC A02/MF A01

A combination of techniques has been used to investigate the condensed-phase thermal decomposition of TATB. STMBMS has been used to identify the thermal decomposition products and their temporal correlations. These experiments have shown that the condensed-phase decomposition proceeds through several autocatalytic pathways. Both low and high molecular weight decomposition products have been identified. Mono-, di-, and tri-furazans products have been identified and their temporal behaviors are consistent with a stepwise loss of water. AFM has been used to correlate the decomposition chemistry with morphological changes occurring as a function of heating. Patches of small 25-140 nm round holes were observed throughout the lattice of TATB crystals that were heated briefly to 300 C. It is likely that these holes show where decomposition reactions have started. Evidence of decomposition products have been seen in TATB that has been held at 250 C for one hour. DOE

As part of an effort to predict the chemical stability of metal oxide catalysts under methane combustion process conditions, a thermodynamic data base was developed for the relevant condensed and gaseous species of the single oxides of Al, Ba, Ca, Ce, Co, Cr, Cu, Fe, K, La, Mg, Mn, Na, Ni, Pd, Pt, Si, Sr, Ti, Zn, and Zr and for their corresponding gaseous metal hydroxide and oxyhydroxide species. The data base is used with the STANJAN computer code to calculate chemical equilibrium compositions for complex metal oxide mixtures under combustion conditions. These gaseous and solid phase compositions can predict catalyst component volatilities and chemical interactions that affect the operating lifetime of catalysts. NTIS

REDUCTION OF NITRIC OXIDE OVER PLATINUM, RHODIUM AND PLATINUM-RHODIUM SINGLE CRYSTAL SURFACES Ph.D. Thesis
J. Siera 11 Nov. 1992 149 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-230092) Avail: Issuing Activity (National Technical Information Service (NTIS))

Although platinum and rhodium are introduced separately in the three-way catalyst, it is established that Pt-Rh alloy particles are formed during its performance. Despite the widespread use of the three-way catalyst and the intensive research on the catalytic properties of the pure metals, relatively little is known about the alloy system. Results are described for the NO-H2, NO-NH3, CO-O2, and CO-NO reactions on the surfaces of Pt, Rh, and Pt-Rh alloy single crystals. NTIS

SALI CHEMICAL ANALYSIS OF PROVIDED SAMPLES Final Report
Christopher H. Becker Aug. 1993 18 p
(Contract SRI-1-1EH-46755; SRI Proj. 3557)
(NASA-CR-194138; NAS 1.26:194138; MP-93-164) Avail: CASI HC A03/MF A01

SRI has completed the chemical analysis of all the samples supplied by NASA. The final batch of four samples consisted of: one inch diameter MgF2 mirror, control 1200-ID-FL3; one inch diameter neat resin, PMR-15, AO171-IV-55, half exposed and half unexposed; one inch diameter chromic acid anodized, EOIM-3 120-47 aluminum disc; and AO-exposed and unexposed samples of fullerene extract material in powdered form, pressed into In foil for analysis. Chemical analyses of the surfaces were performed by the surface analysis by laser ionization (SALI) method. The analyses emphasize surface contamination or general organic composition. SALI uses nonselective photoionization of sputtered or desorbed atoms and molecules above but close (approximately one mm) to the surface, followed by time-of-flight (TOF) mass spectrometry. In these studies, we used laser-induced desorption by 5-ns pulse-width 355-nm light (10-100 mJ/sq cm) and single-photon ionization (SPI) by coherent 118-nm radiation (at approximately 5 x 10(exp 5) W/sq cm). SPI was chosen primarily for its ability to obtain molecular information, whereas multiphoton ionization (not used in the present studies) is intended primarily for elemental and small molecule information. In addition to these four samples, the Au mirror (EOIM-3 200-11, sample four) was depth profiled again. Argon ion sputtering was used together with photoionization with intense 355-nm radiation (35-ps pulsewidths). Depth profiles are similar to those reported earlier, showing reproducibility. No chromium was found in the sample above noise level; its presence could at most be at the trace level. Somewhat more Ni appears to be present in the Au layer in the unexposed side, indicating thermal diffusion without chemical enhancement. The result of the presence of oxygen is apparently to tie-up/draw out the Ni as an oxide at the surface. The exposed region has a brownish tint appearance to the naked eye. Derived from text

CAPILLARY ELECTROKINETIC SEPARATIONS WITH OPTICAL DETECTION
M. J. Sepaniak 1993 17 p
(Contract DE-FG05-86ER-13613)
(DE94-001639; DOE/ER-13613/45) Avail: CASI HC A03/MF A01

This program seeks the development of capillary electrokinetic separation techniques and associated optical methods of detection. Fundamental studies of pertinent separation and band broadening mechanisms are being conducted, with the emphasis on understanding systems that include highly-ordered assemblies as running buffer additives. The additives include cyclodextrins, affinity reagents, and soluble (entangled) polymers and are employed with capillary electrophoresis, CE and/or micellar electrokinetic capillary chromatography, MECC modes of separation. The utility of molecular modeling techniques for predicting the effects of highly ordered assemblies on the retention behavior of isomeric compounds is under investigation. The feasibility of performing separations using a non-aqueous solvent/fullerene electro- chromatographic system is being explored. The analytical methodologies associated with these capillary separation techniques are being advanced through the development of retention programming instumentation/techniques and new strategies for performing optical detection. The advantages of laser fluorimetry are extended through the inclusion of fluorogenic reagents in the running buffer. These reagents include oligonucleotide intercalation reagents for detecting DNA fragments. Chemiluminescence detection using post-capillary reactors/flow cells is also in progress. Successful development of these separation and detection systems will fill current voids in the capabilities of capillary separation techniques. DOE

SYNTHESIS AND IN-VIVO DETECTION OF BORONATED COMPOUNDS FOR USE IN BNCT
G. W. Kabalka Aug. 1993 18 p
(Contract DE-FG05-89ER-60892)
(DE94-001899; DOE/ER-60892/4) Avail: CASI HC A03/MF A01

Carboranes contain ten boron atoms in a three-dimensional space equivalent to a benzene ring; consequently, the carborane isomers can be utilized to prepare a variety of boron-rich agents for potential use in boron-neutron capture therapy. We developed synthetic methodology suitable for use with carboranes preparing amino acids and other physiologically active compounds of potential use in BNCT. The methodology involves the conversion of simple carboranes into more complex, reactive organometallic reagents which can then be utilized to prepare agents which will target the nuclei of tumor cells. Specific examples include the projected syntheses of boron analogs of known intercolators such as diazaquone (AZQ) which have been proven effective in chemotherapy. We have also synthesized and carried out biodistribution studies of gadolinium labeled liposomes (GLL) which were developed in our laboratory. Gadolinium, like boron-10, has an excellent neutron cross section and is considered to be of potential use in neutron capture therapy. GLL are constructed by adding gadolinium based amphiphiles. DOE

The objective of the report is to discover new methods and materials for the economic storage of methane and for the catalytic conversion of methane to useful chemicals. Methane is one of the most abundant fossil fuels but unlike oil it is expensive to transport as a gas or in a liquid form and it is difficult to convert methane to more useful organic materials. The transport of methane and the use of methane as a fuel, for example for automobile engines, would be greatly assisted if it were possible to find materials which would efficiently undergo reversible uptake of methane under mild conditions. The direct catalytic conversion of methane to dihydrogen and carbon monoxide, to methanol, formaldehyde, or by oxidative coupling to ethene are all examples of highly desirable economic processes. These reactions can in principle be achieved by using selective catalysts. The objectives of this proposal, therefore, are to seek new materials which will undergo efficient reversible uptake of methane or which will act as catalysts for the conversion of methane to useful chemicals. DEVELOPMENT OF INFRARED SENSORS USING ENERGY TRANSFER/ENERGY UPCONVERSION PROCESSES: STUDY OF LASER EXCITED FLUORESCENCE IN RARE EARTH ION DOPED CRYSTALS Final Report
S. K. Nash-Stevenson, B. R. Reddy (Alabama A & M Univ., Normal.), and P. Venkateswarlu (Alabama A & M Univ., Normal.) Feb. 1994 18 p
(NASA-TM-108437; NAS 1.15:108437) Avail: CASI HC A03/MF A01

A summary is presented of the spectroscopic study of three systems: LaF3:Ho(3+), LaF3:Er(3+) and CaF2:Nd(3+). When the D levels of Ho(3+) in LaF3 were resonantly excited with a laser beam of 640 nm, upconverted emissions were detected from J (416 nm), F (485 nm), and E (546 nm) levels. Energy upconverted emissions were also observed from F and E levels of Ho(3+) when the material was excited with an 800 nm near infrared laser. When the D levels of Er(3+) in LaF3 were resonantly excited with a laser beam of 637 nm, upconverted emissions were detected from the E (540 nm) and P (320, 400, and 468 nm) levels. Energy upconverted emissions were also observed from F, E, and D levels of Er(3+) when the material was resonantly excited with an 804 nm near infrared laser. When the D levels of Nd(3+) in CaF2 were resonantly excited with a laser beam of 577 nm, upconverted emissions were detected from the L (360 and 382 nm), K (418 nm), and I (432 nm) levels. Very weak upconverted emissions were detected when this system was irradiated with a near infrared laser. The numbers in parentheses are the wavelengths of the emissions. Author (revised)

NEW CONCEPTS FOR HgI2 SCINTILLATOR GAMMA RAY SPECTROSCOPY Technical Status Report, 1 Sep. - 30 Nov. 1993
Jan S. Iwanczyk 14 Jan. 1994 15 p
(Contract NAS7-1204)
(NASA-CR-194819; NAS 1.26:194819) Avail: CASI HC A03/MF A01

The primary goals of this project are development of the technology for HgI2 photodetectors (PD's), development of a HgI2/scintillator gamma detector, development of electronics, and development of a prototype gamma spectrometer. Work on the HgI2 PD's involved HgI2 purification and crystal growth, detector surface and electrical contact studies, PD structure optimization, encapsulation and packaging, and testing. Work on the HgI2/scintillator gamma detector involved a study of the optical - mechanical coupling for the optimization of CsI(Tl)/HgI2 gamma ray detectors and determination of the relationship between resolution versus scintillator type and size. The development of the electronics focused on low noise amplification circuits using different preamp input FET's and the use of a coincidence technique to maximize the signal, minimize the noise contribution in the gamma spectra, and improve the overall system resolution. IN SITU AND EX SITU SPECTROELECTROCHEMICAL AND X RAY ABSORPTION STUDIES ON RECHARGEABLE, CHEMICALLY-MODIFIED AND OTHER MnO2 MATERIALS
B. E. Conway (Ottawa Univ., Ontario.), D. Qu (Ottawa Univ., Ontario.), and J. McBreen (Ottawa Univ., Ontario.) 1992 24 p Presented at the NATO Advanced Research Workshop, Maderia, Portugal, 19 Dec. 1992
(Contract DE-AC02-76CH-00016)
(DE94-001387; BNL-49477; CONF-921277-3) Avail: CASI HC A03/MF A01

A combined series of in situ and ex situ UV spectroelectrochemical and X-ray absorption studies have been made on MnO2, chemically-modified by small amounts of Bi(3), and comparatively on other MnO2 materials such as a blank (Bi-free) and (gamma)-MnO2. These procedures are applied in order to follow the oxidation-states of Bi and of Mn during the course of discharge and recharge of MnO2 as a battery cathode material and the extents of rechargeability that can be achieved with such materials. The presence of Bi appears to provide a preferred 'heterogeneous' discharge/recharge pathway involving a soluble Mn(3) intermediate, over the alternative 'electron-proton' hopping, solid-state mechanism. From XAS results, it is concluded that presence of Bi, although not affecting the O-coordination, does influence the Mn-Mn coordination, determining the way the MnO2 coordination octahedra are connected. TOTAL LIGHT LOSS OPTIC SPECTROSCOPY: PROGRESS TOWARDS A FIBER OPTIC RAMAN ORGANIC VAPOR SENSOR
K. R. Kyle, T. M. Vess, and S. M. Angel Sep. 1993 15 p Presented at the SPIE International Symposium on Optical Tools for Manufacturing and Advanced Automation, Boston, MA, 7-10 Sep. 1993
(Contract W-7405-eng-48)
(DE94-002545; UCRL-JC-115046; CONF-9309199-11) Avail: CASI HC A03/MF A01

A Raman probe has been developed utilizing a single optical fiber as both a light pipe and an active sensing element. By coating a small segment of the surface of an exposed glass fiber core with a thin polymer film, an inverted waveguide is formed where light transmitted down the fiber is stripped out of the core and into the polymer film. The polymer coating is used both as a waveguide and as a medium for concentrating small organic molecules to be interrogated by Raman spectroscopy. The ability of the fiber optic thin film waveguide probe to detect organic vapors is demonstrated. The utility of the probe in the detection of nonaqueous phase liquids (NAPL's) is also described. STUDY OF STREAMWISE VORTICITY-STIRRED COMBUSTION
William T. Peschke and John B. McVey Dec. 1993 74 p Sponsored by NASA. Lewis Research Center Original contains color illustrations
(Contract DAAL03-89-C-0018)
(NASA-CR-194450; NAS 1.26:194450; UTRC-R93-958160-1; ARL-CR-141) Avail: CASI HC A04/MF A01; 10 functional color pages

Experiments were conducted to establish the effects of the introduction of streamwise vorticity in combusting flows modeling those developed within small gas turbine engines. The objective of the effort was to determine whether this combustion concept has the potential for improving the volumetric heat release rates that characterize these engines. Water flow-visualization tests were performed to evolve lobed mixer configurations that, while generating vortex arrays within both the primary and secondary streams, would also provide rapid intermixing between the streams. These experiments resulted in the definition of enhanced-mixing configurations that were characterized, according to air bubble and dye trajectories, by strong interactions between the two streams. These interactions induced a substantial vertical interchange of primary and secondary fluids. Intermingling of the two fluids occurred throughout a region covering 80 percent of the height of the duct within distances from the lobe mixer trailing edge ranging from approximately one-half to one duct height. Combustion experiments were carried out in a high-pressure (7 atm) combustion apparatus using lobe-mixer combinations that exhibited the ability to induce rapid interchange between the primary and secondary streams. Direct observation and gas sampling were employed to characterize the fuel-air ratio distribution effected by the mixers. Flame geometries were compared with those developed during shear-layer combustion occurring downstream from a conventional splitter plate. The results show that the lobed mixers induce a rapid relocation of the fuel-air mixture entering the combustion test section. As contrasted with the 5- to 7-degree flame front angles that occurred during shear layer combustion, the flame front angles developed during combustion using the lobed mixers were more than twice as great, attaining levels approaching 20 degrees. STABILITY OF PREMIXED LAMINAR FLAMES IN A STAGNATION POINT FLOW TO GENERAL DISTURBANCES Final Report, 1 May 1991 - 30 Apr. 1993
Thomas Jackson 30 Apr. 1993 8 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0180-91)
(AD-A273429; AFOSR-93-0872TR) Avail: CASI HC A02

The researchers completed a stability analysis of the stagnation point flow for a general class of disturbances expressed an infinite series. They have shown that when truncated at some large N, a finite number of boundary value systems result for the determination of the growth rate and the flame shape that depends on N, on the cross stream wavenumber, and on all the relevant physiochemical parameters. The stability results thus obtained reduce to those of Kim and Matalon (1990) when N = O and extend them to include corrugations in the direction of stretch with wave number proportional to N. The results are discussed in terms of the Lewis number which is related to the mixture composition and the rate of strain experiences by the flame. This work was recently presented in the Fourth International Conference on Numerical Combustion held in St. Petersburg, FL and has recently been published in Combustion Science Technology. DTIC

We report contact potential difference (CPD) measurements of n-alkanethiol self-assembling monolayers (SAM's) adsorbed to Au substrates using an organomercaptan-modified Au probe. Our results demonstrate for the first time the feasibility and importance of controlling the chemical properties of force microscope probe surfaces. Moreover, control over the chemical characteristics of the probe provides a basis for distinguishing between chemically distinct surface features with nanometer resolution in force microscopy. We show that CPD values obtained using Au probes modified with methyl-terminated SAM's are stable and reproducible, whereas identical unmodified probes yield highly variable data. Our experimentally determined CPD values are in qualitative agreement with calculated CPD's for several Omega-terminated SAM's. DTIC

ELECTROCHEMICAL BEHAVIOR OF ION-PLATED TIN AND Cu-Cr COATINGS Final Report
Y. W. Lee, M. Metzger, and J. M. Rigsbee Sep. 1993 41 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273411; USACERL-TR-FM-93/16) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The electrochemical (corrosion) behaviors of titanium nitride (TiN) and metastable copper-chromium (Cu-Cr) alloy coatings grown on glass, aluminum, and copper substrates using a plasma-assisted physical vapor deposition (ion-plating) technique were investigated. Various polarization techniques were used for corrosion tests in oxygen-saturated and deaerated 5 percent Na2SO4 and 3.5 percent NaCl solutions of two different acidities (pH--6 and 3). The structure, chemistry, and morphology of the coating surfaces before and after corrosion testing were analyzed with scanning electron microscope, x-ray diffraction, Auger, and x-ray photoelectron spectroscopic techniques. Titanium nitride coatings are chemically passive but do not provide effective protection for metallic substrates, under conditions involving pitting corrosion, due to the presence of pinholes in the as-deposited TiN coatings. The inherent properties of TiN do appear suitable for electromagnetic interference/electromagnetic pulse shield applications provided the problem of film defects (porosity, pinholes) can be solved or if the substrate type and corrosion conditions are such that passivation of the substrate surface occurs. Cu-Cr alloy coatings show a general corrosion behavior, with corrosion rates of a few mm per year at the free corrosion potential, which is unsatisfactory for a thin film coating application. DTIC

ADSORPTION, DESORPTION, AND DECOMPOSITION OF HCl AND HBr ON Ge(100): COMPETITIVE PAIRINGAND NEAR-FIRST-ORDER DESORPTION KINETICS
Mark P. DEvelyn, Yuemei L. Yang, and Stephen M. Cohen Nov. 1993 38 p
(Contract N00014-91-J-1550)
(AD-A273504; TR-20-ONR) Avail: CASI HC A03/MF A01

We have investigated the surface chemistry of coadsorbed hydrogen and halogen atoms on Ge(100), produced by dissociative chemisorption of HCL and HBr, by temperature-programmed desorption. The initial sticking probability, S(sub 0), for HCL decreases from 0.6 at a substrate temperature of 270 K to 0.05 at 400 K, indicative of a precursor state to adsorption. For HBr S(sub 0) is constant at 0.7 over the same temperature range. A fraction, f, of adsorbed hydrogen atoms desorb associatively as H2 near 570 K, while the remaining (1-f) H atoms recombine with adsorbed halogen atoms and desorb as the hydrogen halide (HX) near 580 - 590 K. The activation energies for desorption of H2, HCL, and HBr are all approximately 40 kcal/mol. For both HCL and HBr, f is 0.7 at low initial coverage and decreases slightly to 0.6 at saturation. The fraction f of adsorbed halogen atoms left on the surface following the competitive desorption of H2 and HX desorb as the dihalides GeC12 and GeBr2 near 675 K and 710 K, respectively. Desorption of H2, HCL, and HBr occurs with near-first-order kinetics, similar to the behavior of hydrogen adsorbed alone, which we attribute to preferential pairing induced by the pi bond on unoccupied Ge dimers. We introduce and solve a generalized doubly-occupied dimer model incorporating competitive pairing of H+H, H+X, and X+X on Ge dimers to explain the near-first order kinetics. The model quantitatively accounts for both the desorption kinetics and the relative yields of H2 and HX with pairing energies of = approximatetely kcal/mol. DTIC

LPCVD OF InN ON GaAs(110) USING HN3 AND TMIn: COMPARISON WITH Si(100) RESULTS Technical Report
Y. Bu and M. C. Lin 7 Dec. 1993 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1235)
(AD-A273555; TR-22) Avail: CASI HC A02

Low-pressure chemical vapor deposition (LPCVD) of InN and laser-assisted LPCVD on GaAs(110) and Si(100) using HN3 and trimethyl indium (TMIn) has been studied with XPS, UPS, and SEM. Without 308-nm excimer laser irradiation, InN film was built on the GaAs but not on Si surface under the present low-pressure conditions. When the photon beam was introduced, InN films with In:N atomic ratio of 1.0 +/- 0.1 and a thickness of more than 20 A (the limit of the electron escaping depth for the In(3d) x ray photoelectrons) were formed on Si(100) surface. In both cases, the formation of surface nitrides at the initial film growth processes was clearly indicated in the XP spectra. The He(II) UP spectra taken from InN films on GaAs and Si are nearly identical and agree well with the result of a pseudo-potential calculation for the InN valence band. The corresponding SEM pictures showed smooth InN films on GaAs(110), while grains with diameter of approximately 100 nm were observed for InN on Si(100). DTIC

DESIGN OF NOVEL CATALYSTS FOR THE PARTIAL OXIDATION OF METHANE TO METHANOL Annual Report, Jan. - Dec. 1992
G. J. Hutchings, R. W. Joyner, and C. R. A. Catlow (Royal Institution of Great Britain, London.) Jan. 1993 82 p
(Contract GRI-5091-260-2141)
(PB94-114212; GRI-93/0267) Avail: CASI HC A05/MF A01

This work has three key objectives: to identify factors conducive to synergy in selective methane oxidation, by examination, using both experimental and theoretical methods, of the activation of methane, oxygen, methanol, and formaldehyde over a range of catalysts; to identify the role of surface defects and their interaction with surface structure in the catalytic activation of methane; and to apply the information obtained in the design of selective, active catalysts for the conversion of methane to methanol or formaldehyde at temperatures less than approximately 500 C. POTENT SOLVENTS FOR C60 AND THEIR UTILITY FOR THE RAPID ACQUISITION OF 13CNMR DATA FOR FULLERENES Technical Report No. 27
Walter A. Scrivens and James M. Tour 22 Nov. 1993 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-3062)
(AD-A273349; TR-27) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Described are several solvents for the dissolution of fullerenes. The two best solvents found were 1,2-dichlorobenzene and 1-methylnaphthalene which dissolve C60 up to 24.6 and 33.2 mg/mL, respectively. The solubility data was obtained gravimetrically. Precipitates were obtained when C60 was treated with 1,3,5-trimethylbenzene or 1,2,4-trichlorobenzene. Scanning electron micrographs and thermogravimetric analysis data were obtained on the precipitates and compared to the data obtained for pure C60. The efficacy of 1,2-dichlorobenzene and 1-methylnaphthalene as 13C NMR solvents for fullerene analysis was demonstrated as well as the utility of 1,2-dichlorobenzene for the extraction of higher fullerenes from soot. LABORATORY DETECTION OF C5S BY PULSED-DISCHARGE-NOZZLE FOURIER-TRANSFORM MICROWAVE SPECTROSCOPY
Yasuko Kasai, Kinichi Obi, Yasuhiro Oshima, Yasuhiro Hirahara, Yasuki Endo, Kentaro Kawaguchi, and Akinori Murakami 1993 15 p
(JTN-94-80519) Avail: CASI HC A03/MF A01

The rotational spectrum of C5S in the X(exp 1)sigma(+) (v = 0) ground state has been observed for the first time using a Fabry-Perot-type Fourier-transform microwave spectrometer combined with a pulsed discharge nozzle. C5S was generated by a discharge in a mixture of CS2 and C2H2 diluted in Ar, and subsequently cooled down to a few K in a supersonic jet. Eight rotational transitions of C5S-32 have been observed in the 5 - 20 GHz region. Three lines for the less abundant S-34 species have also been detected to confirm the carrier of the observed lines to be C5S. Determined spectroscopic constants will allow a deep radio astronomical search for C5S in interstellar clouds and circumstellar envelopes of late-type stars. Author (NASDA)

ELECTROPHORESIS IN OPEN CAPILLARIES: SOME FUNDAMENTAL ASPECTS Ph.D. Thesis
Mariette Theodora Ackermans 1992 159 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95290) Avail: CASI HC A08

Fundamental aspects of the separation process in capillary electrophoresis in open systems with UV detection are reported. The applicability of this technique is considered with the help of pharmaceuticals, which are used in veterinary practice. The principles of electrophoresis are explained and the qualitative and quantitative aspects are explored. The most important phenomena causing peak broadening in capillary electrophoresis, Joule heating, electroosmosis, diffusion, electrodispersion, injection and interactions of the solutes with the capillary wall are described and an estimation of the magnitude of these effects causing peak broadening in a Capillary Zone Electrophoresis (CZE) experiment is made. Characteristics of CZE are given. The determination of several pharmaceuticals with different modes of capillary electrophoresis is given. ESA

CAPILLARY ELECTROPHORESIS OF BIOMOLECULES: THEORY, INSTRUMENTATION AND APPLICATIONS Ph.D. Thesis
Antonius Albertus A. vandeGoor 1992 136 p Sponsored by Netherlands Foundation for Scientific Research
(ETN-94-95297) Avail: CASI HC A07/MF A02

The principles of Capillary Electrophoresis (CE) are discussed. The instrumental aspects are discussed, by describing different set ups using UV and laser induced florescence detection. The characteristics of electroosmosis, which determines the resolution and reproducibility of CE, are described. Different application areas of biomolecules including the chemistry involved for detection, the columns involved for the separation, and systems used for the optimal resolution are described. The analysis of amino acids using CE is dealt with. The possibilities of CE for peptide analysis are discussed and a comparison to liquid chromatographic separation is made. The analysis of oligonucleotides and Deoxyribonucleic Acids (DNA) restriction fragments is considered. ESA

THE STRUCTURE AND CATALYTIC PROPERTIES OF SUPPORTED PLATINUM CATALYSTS Ph.D. Thesis
Marinus Vaarkamp 1993 167 p Sponsored by Amoco Oil Research, Naperville, IL Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95357) Avail: Issuing Activity (European Space Agency (ESA))

The relation between the structure of the metal particles and the metal-support interface, the electronic structure, and the catalytic properties of supported metal catalysts is studied. Attention is limited to platinum supported on two amorphous supports (silica and alumina) and zeolite L. To maximize the effect of the support on the structure of the metal particles, the structure of the metal-support interface, the electronic structure, and the catalytic properties, catalysts were prepared with very small particles. The main characterization method applied is X ray Absorption Spectroscopy (XAS). Improvements to the generally used methods of analysis of the Extended X ray Absorption Fine Structure (EXAFS) are discussed. Systematic errors arising from the used phase and backscattering amplitude are studied and theoretical methods to calculate the phase and backscattering amplitude are evaluated. The sulphur sensitivity of the highly active and selective dehydrocyclization catalyst Pt/BaK-LTL is studied. The structure and morphology of the platinum clusters and the structure of the metal-support interface of Pt/zeolite and Pt/gamma-Al_2O_3 catalysts are studied. The relation between electronic structure and catalytic properties of supported platinum catalysts is studied. The influence of support and reduction temperature on the activity and selectivity of supported platinum crystals in methylcyclopentane ring opening is reported. ESA

MODELLING OF PREMIXED LAMINAR FLAMES Ph.D. Thesis
Rick deLange 1992 166 p
(ETN-94-95317) Avail: CASI HC A08/MF A02

A study whose aim is to model not only flames of pure, or low carbon, gases but also those of natural gas mixtures is presented. One dimensional flames and the determination of the reaction parameters are considered. An approach to describe freely propagating, or adiabatic, flames ruled by a one step reaction is presented. A numerical method suited to model laminar two dimensional flames in a Cartesian system is also presented. The stabilization of a flame on a parallel slit burner is described. This theory describes the influence of cooling, due to the burner rim, on the stand off distance, the distance between the cold burner rim and the flame sheet. The numerical results on stability limits, both near flashback and quenching limits, as well as global flame structure for premixed CH_4/air flame on a parallel plate burner are compared with experimental results. The results are used in a study of the combustion process in the tip of the flame. ESA

THE ELECTROCHEMISTRY OF THE SOLVATED ELECTRON: A STUDY OF ITS PROPERTIES AND OF ITS APPLICATIONS Ph.D. Thesis
Pieterdina J. M. vanAndel-Scheffer 1992 98 p
(ETN-94-95313) Avail: CASI HC A05/MF A02

The electrochemistry of solvated electrons is discussed. The electrochemical generation of solvated electrons in hexamethyl phosphortriamide (HMPA) and in methylamine was investigated. Lithium chloride or lithium bromide was used as the elecrolyte. Because the rotating ring disk electrode (RRDE) technique was used in particular, this technique is described. Attention is paid to the merits of solvated electrons as a powerful reductant in electroorganic synthesis. In HMPA/Li salt solutions, solvated electrons can be cathodically generated at the disk of a RRDE and be oxidized when they reach the ring electrode. The use of this hydrodynamic technique to study several features of electrochemistry is described. It was shown that by means of transit time measurements, information can be obtained about the mobility of solvated electrons in HMPA/Li salt solutions. The reaction of solvated electrons with water and benzene is described. It is shown that various substituted benzylamines can be reduced in methylamine using lithium chloride as electrolyte. ESA

DRYING DEFORMABLE MEDIA: KINETICS, SHRINKAGE AND STRESSES Ph.D. Thesis
Antonius Adrianus J. Ketelaars 1992 117 p Sponsored by Nederlandse Maatschappij voor Energie en Milieu B.V., Netherlands; Koninklijk Verbond van Nederlandse Baksteenfabrikanten, Netherlands; and Nederlandse Dakpannenfabrikanten Corp., Netherlands
(ETN-94-95314) Avail: CASI HC A06/MF A02

A model for drying of clays, which gives special attention to shrinkage and stresses, is developed. The drying kinetics model is developed based on the diffusion equation. Deformations due to shrinkage and stresses are taken into account. Essential in the use of a diffusion equation is a reliable experimental determination of the diffusion coefficient as a function of moisture content. An experimental method for the derivation of the diffusion coefficient, based on accurate measurements of transient moisture concentration profiles, is considered. Results for three clays are included. Results of the traditional method for the determination of the diffusion coefficient, which is based on the use of drying curves, are compared with these results. The influence of shrinkage on drying behavior is studied. Multidimensional simulations are performed in order to get a quantitative idea of the importance of shrinkage in drying of clays. ESA

LIAPUNOV STABILITY IN CHEMICAL ENGINEERING
C. Storey Jul. 1993 35 p Presented at the 2nd International Workshop on Mathematical Modelling in Chemical Engineering, Budapest, Hungary, 11-15 Jul. 1993
(MATHS-Rept-A-184; ETN-94-95227) Avail: CASI HC A03/MF A01

Liapunov stability theory and techniques in chemical engineering are reviewed. Attention is focused on the classical Liapunov methods. The main difficulty with Liapunov's direct method appear to lie in the fact that the stability theorems are sufficient only and in the difficulties involved in generating suitable Liapunov functions. The determination of domains of attraction via this method is also beset with numerical difficulties and gives conservative results. ESA

RELATIONSHIP OF MICROSTRUCTURE AND MECHANICAL PROPERTIES FOR V-Cr-Ti ALLOYS
B. A. Loomis, J. Gazda, L. J. Nowicki, D. L. Smith, and S. Danyluk (Chicago Univ., IL.) Aug. 1993 14 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-001431; ANL/ET/CP-80862; CONF-930928-9) Avail: CASI HC A03/MF A01

Relation of composition, number density, and diameter of precipitates in microstructures of unalloyed V and V-Cr-Ti alloys to the yield strength, hardness, creep stress, and ductile-brittle transition temperature (DBTT) for these materials was determined from analytical electron microscopy analyses of precipitates in these materials and from mechanical properties data. Unalloyed V and V-Cr-Ti alloys with less than or equal to 3 wt. % Ti contained VC and TI(CNO) precipitates that were coherent with the matrix. The most common precipitates in the alloys were Ti(C(1-x-y)N(x)O(y)) that were non-coherent with the matrix. The number density of non-coherent precipitates was maximum in V-3Ti and V-5Cr-3Ti alloys, and the average diameter of non-coherent precipitates was minimum in V-(1 - 3)Ti and V-5Cr-3Ti alloys. The increase of yield strength and hardness of V on alloying with Ti and Cr was shown to be primarily due to coherent precipitate, solute-atom misfit, and shear-modulus difference effects. The creep stress for rupture in 1000 hours was related to the number density of precipitates, whereas the DBTT was related to the volume fraction of precipitates. DOE

FATIGUE CRACK GROWTH RATE STUDIES OF MEDIUM SULFUR LOW ALLOY STEELS TESTED IN HIGH TEMPERATURE WATER
T. A. Auten, S. Z. Hayden, and R. H. Emanuelson (Babcock and Wilcox Co., Alliance, OH.) May 1993 10 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993
(Contract DE-AC12-76SN-00052)
(DE93-040437; KAPL-4761; CONF-930825-6) Avail: CASI HC A02/MF A01

Fatigue crack propagation tests of medium sulfur (0.007 to 0.011 wt %) ASTM A508-Class 2 forgings were performed in deaerated high purity, high temperature water. In general, these forgings did not exhibit environmentally assisted cracking (EAC) in tests at 149C (300F) or at 260C (500F). Lowering the pH did not raise the crack growth rates significantly. However, adding a small amount of oxygenated water to the feedwater increased the fatigue crack growth rates (FCGR) by a factor of about 4. Automated analyses of the sulfide inclusions in polished sections of the forgings supported a previously proposed relationship for susceptibility to EAC. DOE

We have found that aluminum alloys exhibit unusual passivity when exposed to alkaline Li-salt solutions. Observed passivity is due to the formation of a polycrystalline Li2(Al2(OH)6)(sub 2)(center dot)CO3(center dot)3(H2O) film on the aluminum surface. This film is persistent in aggressive environments and provides a significant degree of corrosion protection. On this basis, we have developed a simple non-electrolytic method of forming corrosion resistant coatings in alkaline Li-salt solution. This process is procedurally similar to traditional conversion coating methods, offers desirable properties, and has a low toxic hazard. In this paper, coating methods, coating characterization, and coating properties are presented. Results from parallel test performed with a commercial chromate conversion coatings are presented for comparison. DOE

ANALYSIS OF ALLOY 600 AND X-750 STRESS CORROSION CRACKS
C. D. Thompson, N. Lewis, and H. Krasodomski Jun. 1993 48 p Presented at the Alloy 600 Experts Meeting, Warrenton, VA, 5-9 Apr. 1993
(Contract DE-AC12-76SN-00052)
(DE94-001578; KAPL-4760; CONF-9304146-3) Avail: CASI HC A03/MF A01

A few months ago, KAPL evidence supported the view that Primary or

Pure Water Stress Corrosion Cracking (PWSCC) of Alloy 600 results from a hydrogen mechanism. An analytical Electron Microscope (AEM) analysis of a stress corrosion crack (SCC) crack in an A600 split tube U-bend specimen exposed to primary water at 338 C (640 F) for 462 days is shown. The features which appear to confirm a hydrogen mechanism are as follows: (1) a very narrow (less than 200 A) crack with a sharp tip, nearly free of deposits; (2) no evidence of severe plastic deformation in the region immediately ahead of the crack tip; and (3) a line of small voids preceding the main crack tip, of which the largest is about 5 x 10(exp -6) cm in length. Shen and Shewmon proposed that PWSCC of Alloy 600 occurs due to small microvoids ahead of a main crack tip. The hypothesis is that such voids result from pockets of methane gas formed by the reaction of atomic hydrogen with carbon in the base metal. The voids are about 10 x 10(exp -6) cm diameter, approximately a factor of 2 larger than the largest voids. DOE

MAGNETIC PHASES IN UNiGe
V. Sechovsky (Karlova Univ., Prague, Czechoslovakia.), L. Havela (Karlova Univ., Prague, Czechoslovakia.), and A. Purwanto 1993 10 p Presented at the Actinides 1993, Santa Fe, NM, 19-24 Sep. 1993
(Contract W-7405-eng-36)
(DE94-000793; LA-UR-93-3350; CONF-930905-11) Avail: CASI HC A02/MF A01

Original measurements of 4.2 K magnetization curves and temperature dependence of magnetic susceptibility were completed by an extended study of magnetization, specific heat, and electric resistivity as a function of temperature and magnetic field. Neutron diffraction experiments were also performed on powder and single crystal. The specific heat shows a sharp peak at 41.5 K, corresponding to the first-order phase transition, and a broad anomaly around 50 K. The magnetic structures in UNiGe confirm that the strong bonding of 5f orbitals along the a axis leads to a huge magnetic anisotropy with U magnetic moments perpendicular to this direction. DOE

THE HISTORY OF DEVELOPMENT OF MOLYBDENUM ALLOYS FOR STRUCTURAL APPLICATIONS
J. Wadsworth and J. P. Wittenauer (Lockheed Missiles and Space Co., Palo Alto, CA.) Feb. 1993 26 p Presented at the 122nd Annual Meeting of the Minerals, Metals and Materials Society (TMS), Denver, CO, 21-25 Feb. 1993
(Contract W-7405-eng-48)
(DE94-000389; UCRL-JC-114114; CONF-9302103-5) Avail: CASI HC A03/MF A01

Molybdenum was first isolated as an element in 1893 and found initial commercial application as a filament support for incandescent lamps in 1910. The advent of arc melting practice in the 1940's led to an increase in availability of Mo sheet, bar, and plate products. Alloy development programs were heavily supported starting in the 1950's and several key alloys emerged over the next twenty years that remain in use to the present time such as Mo-TZM, unalloyed Mo, and Mo-Re. In recent years, improved understanding of the role of oxygen and carbide distributions at grain boundaries have led to increased reliability and use of Mo in aerospace products. Current developmental programs in areas of propulsion and energy conversion will ensure the prominent position of Mo as a high-temperature structural material. This paper highlights some of these key developments in the evolution of Mo alloys. DOE

INFLUENCE OF SINTERING ATMOSPHERES ON THE ALUMINUM SINTERING CHARACTERISTICS [INFLUENCIA DE LA ATMOSFERA DE SINTERIZACION EN LAS CARACTERISTICAS DE SINTERIZADO DEL ALUMINIO]
S. Mintzer and S. BermudezBelkys 1993 5 p In SPANISH Presented at the SAM 1993: 17th Metallurgical Sesssions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina, 13-16 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print
(DE93-632412; INIS-AR-013; CONF-9304174) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The aluminum powder (Al) cool compacted (at 95% from theoretical density) which was sintered at 903 K during 4 hours at different atmospheres, oxidizing (air), inert Argon (Ar), Nitrogen (N) and high vacuum is described. The results obtained show: (1) porosity measurements; greater porosity when sintering in Ar and air; (2) metallographic and scanning observations: many fine pores (less than 1 micron) and pore lines distributed at random, at air sintering and greater pores distributed preferentially near the surface, in Ar and N atmospheres; (3) dimensional changes: tendency to contraction of the samples at N and vacuum sintering and expansion in Ar or air; (d) mechanical properties: greater strength and fluence stresses at air and N sintering. The analysis of the results is performed considering sintering modes in presence of an oxide layer and dropped inert gases. DOE

DIFFUSION OF HYDROGEN IN IRON OXIDES [DIFUSION DE HIDROGENO EN OXIDOS DE HIERRO]
P. Bruzzoni and E. Riecke (Max-Planck-Inst. fuer Eisenforschung, Duesseldorf, Germany.) 1993 5 p In SPANISH Presented at the SAM 1993: 17th Metallurgical Sessions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina, 13-16 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print
(DE93-632430; INIS-AR-012; CONF-9304174) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The diffusion of hydrogen in transition metal oxides was recently studied at room temperature through the permeability electrochemical technique. This work studies thin oxide layers grown in air or in presence of oxidizing atmospheres at temperatures up to 200 C. The substrate was pure iron with different superficial treatments. It was observed that these oxides reduce up to three magnitude orders, the hydrogen stationary flux through membranes of usual thickness in comparison with iron membranes free of oxide. DOE

DAMAGE UNDER MONOTONIC OR CYCLIC LOADS OF NEW AlSiFe ALLOYS PREPARED BY THE OSPREY (TM) PROCESS Ph.D. Thesis [ENDOMMAGEMENT SOUS SOLLICITATION MONOTONE OU CYCLIQUE DES NOUVEAUX ALLIAGES AL-SI-FE ELABORES PAR PROCEDE OSPREY (TM)]
Annick Mocellin 1993 259 p In FRENCH Sponsored by Societe Pechiney, France
(ISAL-93-0008; ETN-94-95169) Avail: CASI HC A12/MF A03

The mechanical behavior of AlSiFe alloys obtained by the Osprey (trademark) process is investigated. The microstructure of the AlSiFe is characterized by small grains containing silicon particles and intermetallic compounds. These alloys have a mechanical behavior similar to that of metal matrix composites reinforced with ceramic particles. The resistance to cyclic loads is found to be high. The fracture characteristics are investigated by tensile tests. The results show local plastic deformation between the matrix and the silicon particles, fracture of silicon particles in mode one, grain boundary shear stresses, and final intergranular decoherence of the fractured particles. The fatigue crack propagation behavior is discussed. The effect of the thermal stresses in the damage behavior is calculated by the iterative Eshelby method. A model to explain the phenomena observed is proposed. ESA

IRRADIATION DAMAGE BEHAVIOR OF LOW ALLOY STEEL WROUGHT AND WELD MATERIALS
R. J. Stofanak, T. J. Poskie, Y. Y. Li, and G. L. Wire 1993 7 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993
(Contract DE-AC11-89PN-38014)
(DE94-000519; WAPD-T-2991; CONF-930825-7) Avail: CASI HC A02/MF A01

A study was undertaken to evaluate the irradiation damage response of several different types of low alloy steel: vintage type ASTM A302 Grade B (A302B) plates and welds containing different Ni and Cu concentrations, 3.5% Ni steels similar to ASTM A508 Class four, welds containing about 1% Ni (similar to type 105S), and 3.5% Ni steels with 'super-clean' composition. All materials were irradiated at several different irradiation damage levels ranging from 0.0003 to 0.06 dpa at 232 C (450 F). Complete Charpy V-notch impact energy transition temperature curves were generated for all materials before and after irradiation to determine transition temperature at 41 J (30 ft-lb) or 47 J (35 ft-lb) and the upper shelf energy. Irradiation damage behavior was measured by shift in Charpy 41 J or 47 J transition temperature (Delta TT(sub 41 J) or Delta TT(sub 47J)) and lowering of upper shelf Charpy energy at a given irradiation damage level. It was found that chemical composition greatly influenced irradiation damage behavior; highest irradiation damage (greatest Delta TT) was found in an A302B type weld containing 1.28% Ni and 0.20% Cu while the least damage was found in 3.5% Ni, 0.05% Cu, super-clean wrought materials. Combination of Ni and Cu was found to affect irradiation damage behavior at higher irradiation damage levels in the A302B welds where the 1.28% Ni, 0.20% Cu weld showed more damage than a 0.60% Ni, 0.31% Cu weld. For the 3.5% Ni steels, fabrication influenced irradiation behavior in that a silicon killed material showed greater irradiation damage than a low silicon material. In general, the 3.5% Ni materials with low copper showed less irradiation damage than the A302B materials. DOE

INTERPLAY OF MAGNETIC AND SUPERCONDUCTING HEAVY FERMION GROUND STATES
R. H. Heffner 1993 7 p Presented at the 1993 International Workshop on Low Energy Muon Science, Santa Fe, NM, 4-8 Apr. 1993
(Contract W-7405-eng-36)
(DE94-000680; LA-UR-93-3473; CONF-9304145-3) Avail: CASI HC A02/MF A01

This talk will focus recent developments in the understanding of heavy fermion (HF) superconductors and the role that positive muon spin relaxation (mu SR) studies have played in helping to elucidate their properties. As illustrations, two systems will be discussed: UPd2Al13, one of the most recently discovered HF superconductors, which also displays coexisting magnetic order, and UBe13 doped with small quantities of Th substituted for U, which displays an interplay between its superconducting and magnetic ground states, leading to multiple superconducting states. EFFECTS OF NEUTRON IRRADIATION AND HYDROGEN ON DUCTILE-BRITTLE TRANSITION TEMPERATURES OF V-Cr-Ti ALLOYS
B. A. Loomis, H. M. Chung, L. J. Nowicki, and D. L. Smith Aug. 1993 14 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print and microfiche quality
(Contract W-31-109-eng-38)
(DE94-001466; ANL/ET/CP-80889; CONF-930928-8) Avail: Issuing Activity (Department of Energy (DOE))

The effects of neutron irradiation and hydrogen on the ductile-brittle transition temperatures (DBTT's) of unalloyed vanadium and V-Cr-Ti alloys were determined from Charpy-impact tests on 1/3 ASTM standard size specimens and from impact tests on 3-mm diameter discs. The tests were conducted on specimens containing less than 30 appm hydrogen and 600-1200 appm hydrogen and on specimens after neutron irradiation to 28-46 dpa at 420, 520, and 600 C. The DBTT's were at a minimum (less than -220 C) for V-(105)Ti alloys under for V-4-Cr-4Ti alloy with less than 30 appm hydrogen. The effect of 600-1200 appm hydrogen in the specimens was to raise the DBTT's by 100-150 C. The DBTT's were minimum (less than -220 C) for V-(1-5)Ti alloys and V-4-Cr-4Ti alloys after neutron irradiation. DOE

TENSILE PROPERTIES OF 21-6-9 STAINLESS STEEL AT ELEVATED TEMPERATURES
S. G. Torres and G. A. Henshall Oct. 1993 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-001852; UCRL-ID-114590) Avail: CASI HC A03

Tensile properties of Type 21-6-9 austenitic stainless steel were measured at temperatures ranging from ambient to 1200 C at a strain rate of 6.67 x 10(exp -4) /s. Data show that yield stress decreases rapidly from room temperature to about 300 C, followed by a nearly constant value in the 'plateau' region from 300 to 600 C. Beyond the plateau, there is a more rapid drop in yield stress as temperature increases. Ultimate tensile stress shows a plateau between 300 and 700 C, which may be caused by solutes. 21-6-9 stainless steel has excellent ductility, with the elongation to failure ranging from 55 to 95%. It appears that there is a local minimum in the ductility at approximately 700 C. Results are compared with earlier results of Kassner and co-workers. DOE

TEXTURE GRADIENT EFFECTS IN TANTALUM
S. I. Wright, G. T. Gray, III, and A. J. Beaudoin (Reynolds Metals Co., Richmond, VA.) 1993 7 p Presented at the International Conference on Textures of Materials, Clausthal, Germany, 20-24 Sep. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-000689; LA-UR-93-3454; CONF-9309231-4) Avail: CASI HC A02

The effects of inhomogeneities in texture on the mechanical response of a tantalum plate were investigated. Through-thickness compression samples exhibited an hourglass shape after deformation. The compression tests were modeled using a finite-element approach. A polycrystal plasticity model is embedded at each element of the mesh enabling the simulation to account for the spatial distribution of texture and its evolution. The texture was characterized using spatially specific individual lattice orientation measurements. The orientations were measured using automatic analysis of electron backscatter Kikuchi diffraction patterns. The influence of the spatially nonuniform distribution of texture on the experimental and simulated results is discussed. This work demonstrates the capability of currently available tools for characterizing inhomogeneous microstructures and modeling the effects of variations in texture on mechanical behavior. DOE

INTERNAL FRICTION ASSOCIATED WITH DISLOCATION RELAXATIONS IN VIRGIN MARTENSITE
L. Yong Apr. 1993 60 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-226280; ISBN-951-22-1523-3) Avail: CASI HC A04

Four internal friction peaks were observed during heating of virgin lenticular martensite from 82 to 350 K. Investigations on the effects of alloying contents and test conditions on the internal friction peaks have shown that there are three internal friction peaks exhibiting relation features, which can be attributed to the dislocation relaxation processes. Two of them can be attributed to the generation of kink-pairs along non-screw and screw dislocations, and one is due to the interaction between non-screw dislocations and carbon atoms. NTIS

EFFECT OF NEUTRON IRRADIATION ON TENSILE PROPERTIES OF V-Cr-Ti ALLOYS
B. A. Loomis, L. J. Nowicki, and D. L. Smith Aug. 1993 15 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-001433; ANL/ET/CP-80863; CONF-930928-7) Avail: CASI HC A03/MF A01

The tensile properties of V-4Cr-4Ti, V-9Cr-5Ti, V-14Cr-5Ti, V-3Ti-1Si, V-5Ti, and V-18Ti alloys were determined at 25, 420, 520, and 600 C after neutron irradiation to 28-46 dpa at 420, 520, and 600 C. The yield strength of the unirradiated alloys increased significantly (approximately 50%) on neutron irradiation. Irradiation hardening of the alloys at 25 C after irradiation at 420 C was on the order of V-18Ti less than V-3Ti-1Si less than V-5Ti less than V-4Cr-4Ti less than V-9Cr5Ti less than V-14Cr-5Ti. The total elongation of the irradiated alloys at 25 C after irradiation at 420 C ranged from 3% to 11% with total elongation of the alloys on the order of V-14Cr-5Ti less than V-9Cr-5Ti less than V-3Ti-1Si less than V-5Ti less than V-4Cr-4Ti less than V-18Ti. The total elongation of the alloys at 600 C after irradiation ranged from 11% to 23% with total elongation of the alloys on the order of V-14Cr-5Ti less than V-9Cr-5Ti less than V-4Cr-4Ti less than V-5Ti less than V-3Ti-1Si less than V-18Ti. THERMALLY ACTIVATED LOW TEMPERATURE CREEP AND PRIMARY WATER STRESS CORROSION CRACKING OF NiCrFe ALLOYS

M. M. Hall, Jr. 1993 27 p Presented at the Alloy 600 Experts Meeting, Warrenton, VA, 5-9 Apr. 1993
(Contract DE-AC11-93PN-38195)
(DE94-001756; WAPD-T-3008; CONF-9304146-2) Avail: CASI HC A03/MF A01

A phenomenological stress corrosion cracking-crack growth rate (SCC-CGR) model is developed based on an a priori assumption that the SCC-CGR is controlled by low temperature creep (LTC). This mode of low temperature time dependent deformation occurs at stress levels above the athermal flow stress by a dislocation glide mechanism that is thermally activated and may be environmentally assisted. The SCC-CGR model equations developed contain thermal activation parameters descriptive of the dislocation creep mechanism. Thermal activation parameters are obtained by fitting the CGR model to SCC-CGR data obtained on Alloy 600 and Alloy X-750. These SCC-CGR activation parameters are compared to LTC activation parameters obtained from stress relaxation tests. When the high concentration of hydrogen at the tip of an SCC crack is considered, the SCC-CGR activation energies and rate sensitivities are shown to be quantitatively consistent with hydrogen reducing the activation energy and increasing the strain rate sensitivity in LTC stress relaxation tests. Stress dependence of SCC-CGR activation energy consistent with that found for the LTC activation energy. Comparisons between temperature dependence of the SCC-CGR stress sensitivity and LTC stress sensitivity provide a basis for speculation on effects of hydrogen and solute carbon on SCC crack growth rates. DETERMINATION OF FIBER-MATRIX INTERFACE FAILURE PARAMETERS FROM OFF-AXIS TESTS

Rajiv A. Naik (Analytical Services and Materials, Inc., Hampton, VA.) and John H. Crews, Jr. Oct. 1993 30 p
(RTOP 505-63-50-04)
(NASA-TM-109043; NAS 1.15:109043) Avail: CASI HC A03/MF A01

Critical fiber-matrix (FM) interface strength parameters were determined using a micromechanics-based approach together with failure data from off-axis tension (OAT) tests. The ply stresses at failure for a range of off-axis angles were used as input to a micromechanics analysis that was performed using the personal computer-based MICSTRAN code. FM interface stresses at the failure loads were calculated for both the square and the diamond array models. A simple procedure was developed to determine which array had the more severe FM interface stresses and the location of these critical stresses on the interface. For the cases analyzed, critical FM interface stresses were found to occur with the square array model and were located at a point where adjacent fibers were closest together. The critical FM interface stresses were used together with the Tsai-Wu failure theory to determine a failure criterion for the FM interface. This criterion was then used to predict the onset of ply cracking in angle-ply laminates for a range of laminate angles. Predictions for the onset of ply cracking in angle-ply laminates agreed with the test data trends. Author

PHASE TRANSFORMATIONS IN Cu-Zr MULTILAYERS

T. P. Weihs, T. W. Barbee, Jr., and M. A. Wall Apr. 1993 8 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract W-7405-eng-48)
(DE94-000393; UCRL-JC-113810; CONF-930405-43) Avail: CASI HC A02/MF A01

A study of phase transformations is reported for Cu-rich, Cu-Zr multilayer foils synthesized using magnetron sputter deposition and annealed using a differential scanning calorimeter. The foils range in composition from 1.6 to 9.0 at% Zr and consist of alternate layers of polycrystalline Cu and Zr. Differential scanning calorimetry, X-ray analysis, and electron microscopy were used to examine three distinct reactions in the foils: a mixing and an amorphization of the Cu and the Zr, a crystallization of this amorphous phase to the metastable intermetallic Cu51Zr14, and a transformation of the Cu51Zr14 phase into the equilibrium phase Cu9Zr2. The as-deposited layering remained stable during the first two reactions and then broke down in the third reaction as large grains of Cu9Zr2 encompassed the smaller Cu grains. Heats of the reactions and activation energies of these reactions are measured and are compared to values reported for bulk samples. The measured heats provide evidence that amorphous Cu-Zr alloys phase separate and that mixing and short range ordering produce 3.5 times more heat than long range ordering produces when Cu and Zr react and form Cu51Zr14. DOE

DETERMINATION OF THE COMPATIBILITY BETWEEN STRUCTURAL ALLOYS AND MOLTEN METALS AT HIGH TEMPERATURES

G. A. Henshall, L. M. Wagner, B. A. Westfall, and R. P. Kershaw Aug. 1993 20 p
(Contract W-7405-eng-48)
(DE94-000954; UCRL-ID-114706) Avail: CASI HC A03/MF A01

The experimental methods for determining high-temperature compatibility between structural alloys and molten metals, particularly braze alloys, have been established. The structural alloys of interest are formed or machined into small crucibles into which the metal to be melted is placed. This system is placed in a furnace which typically will have a vacuum or inert gas environment; other atmospheres are possible as well. Multiple crucibles are exposed for various times and temperatures. Following cooling, a visual examination for loss of containment is performed. Each crucible is then sectioned and examined metallographically to document any loss in thickness of the crucible or any reactions between the materials. These procedures are fairly simple and require only common laboratory equipment; costs, therefore, are kept low. These experimental techniques were refined for use in determining the compatibility of both commercially pure vanadium and 21-6-9 stainless steel with a 92.5% Pb-5% In-2.5% Ag braze alloy. Both the vanadium and the stainless steel contained the molten Pb-In-Ag alloy for exposures ranging from 1000 C for 10 minutes up to 1200 C for 2 hours. DOE

QUANTITATIVE ANALYSIS IN THE Al-Mg-Si SYSTEM WITH SMALL AMOUNTS OF Mg AND Si

Y. Tang (Norges Tekniske Hoegskole, Trondheim.), H. K. Nylund, R. Hoeier (Norges Tekniske Hoegskole, Trondheim.), and N. Ryum 28 Jan. 1993 5 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-201499; STF19-A92031) Avail: CASI HC A01

In the commercial Al-Mg-Si system, detailed knowledge of the precipitation rate of the Mg2Si needles and the dissolution rate of the original Mg2Si particles are of practical importance. However, due to low Mg and Si contents, experimental studies of the concentration gradients are difficult, especially if high spacial resolution is required. In these preliminary studies, the use of the energy dispersive x-ray (EDS) and electron energy loss spectroscopy (PEELS) methods have been investigated. The studies indicate that Mg may be quantified in the 0.6-1.0% regime with PEELS but not with EDS. The reverse is true for Si. NTIS

THEORY OF EXTRUSION: ADVANCES AND CHALLENGES

S. Stoeren (Norges Tekniske Hoegskole, Trondheim.) 27 Nov. 1992 12 p Sponsored by Hydro Aluminum A/S Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-201572; STF20-A92187) Avail: Issuing Activity (National Technical Information Service (NTIS))

Plane-strain slip-line field theory, upper bound analysis and visioplasticity technique form the basis for the mechanics of extrusion. Bishop pointed out in 1957 that to make the theory useful in practice, one had to use the mechanics of extrusion to quantify phenomena that were primarily metallurgical, such as speed limit phenomena, flow resistance, the evolution of microstructure and properties of the extrudate. The practical part of the review focuses on unlubricated extrusion of aluminum alloys and on product and process development related to aluminum extrusions. NTIS

GRAIN-BOUNDARY MICROCHEMISTRY AND INTERGRANULAR CRACKING OF IRRADIATED AUSTENITIC STAINLESS STEEL

H. M. Chung, W. E. Ruther, J. E. Sanecki, and T. F. Kassner Sep. 1993 10 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993
(Contract W-31-109-eng-38)
(DE94-000466; ANL/ET/CP-80756; CONF-930825-9) Avail: CASI HC A02/MF A01

Constant-extension-rate tensile tests and grain-boundary analysis by Auger electron spectroscopy were conducted on high- and commercial-purity (HP and CP) Type 304 stainless steel (SS) specimens from irradiated BWR components to identify mechanisms of irradiation-assisted stress corrosion cracking (IASCC). Susceptibility to intergranular fracture could not be correlated with radiation-induced segregation of impurities such as Si, P, C, or S, but a correlation was obtained with grain-boundary Cr concentration, indicating a role for Cr depletion. Grain-boundary chemistry was conducted on BWR neutron absorber tubes fabricated from two similar heats of HP Type 304 SS of virtually identical bulk chemical composition but exhibiting different susceptibility to IASCC after irradiation to approximately 2 x 10(exp 21) n/sq cm (E is greater than 1 MeV). Grain-boundary concentrations of Cr, Ni, Si, P, S, and C of the cracking-resistant and -susceptible HP heats were virtually identical. However, grain boundaries of the cracking-resistant material contained less N and more B and Li. This observation indicates that, besides the deleterious effect of grain-boundary Cr depletion, synergism between grain-boundary segregation of N and B and transmutation to H and Li plays an important role in IASCC. CHARACTERIZATION AND DURABILITY TESTING OF PLASMA-SPRAYED ZIRCONIA-YTTRIA AND HAFNIA-YTTRIA THERMAL BARRIER COATINGS. PART 2: EFFECT OF SPRAY PARAMETERS ON THE PERFORMANCE OF SEVERAL HAFNIA-YTTRIA AND ZIRCONIA-YTTRIA COATINGS

Robert A. Miller and George W. Leissler (Sverdrup Technology, Inc., Brook Park, OH.) Washington Mar. 1993 20 p
(Contract NAS3-25266; RTOP 505-63-5A)
(NASA-TP-3296; E-7152; NAS 1.60:3296) Avail: CASI HC A03/MF A01

This is the second of two reports which discuss initial experiments on thermal barrier coatings prepared and tested in newly upgraded plasma spray and burner rig test facilities at LeRC. The first report, part 1, describes experiments designed to establish the spray parameters for the baseline zirconia-yttria coating. Coating quality was judged primarily by the response to burner rig exposure, together with a variety of other characterization approaches including thermal diffusivity measurements. That portion of the study showed that the performance of the baseline NASA coating was not strongly sensitive to processing parameters. In this second part of the study, new hafnia-yttria coatings were evaluated with respect to both baseline and alternate zirconia-yttria coatings. The hafnia-yttria and the alternate zirconia-yttria coatings were very sensitive to plasma-spray parameters in that high-quality coatings were obtained only when specific parameters were used. The reasons for this important observation are not understood. Author (revised)

JBK-75 STAINLESS STEEL MACHINABILITY STUDY

A. P. McManigle and A. W. Simonis 2 Sep. 1993 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC34-90DP-62349)
(DE94-002268; RFP-4627) Avail: CASI HC A03

The study on forgings characterized machinability of the material by varying cutting speeds and feed-rates utilizing four tools for the roughing operation and four tools for the semi-finish operation. Tools tested were obtained from four manufacturers. Twelve parts were machined utilizing an experimental design to determine all possible interactions between cutting speeds and feed-rates. To evaluate the machinability of the material, quantitative measures in tool life, tool wear, surface finish, chip control, and material removal rates were analyzed. Benefits gained from this study are: higher material removal rates, longer tool life, minimal tool wear, improved chip control and reliability, increased productivity, and cost minimization. DOE

EXPLORATORY REPORT NICKEL AND NICKEL COMPOUNDS

W. Slooff, P. F. H. Bont (Resources Planning Consultants B.V., Delft, Netherlands.), J. A. Janus, and B. Loos Oct. 1992 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-223998; RIVM-710401017) Avail: CASI HC A04

The report contains general information on nickel and nickel compounds concerning the existing standards, emissions, exposure levels, and effect levels. The document is to be considered as a start for the national discussion during an exploratory meeting on integrated criteria documents. Pure nickel is not produced in the Netherlands, but nickel and nickel compounds are widely used. The most important sources of emissions to air are refineries and usage of diesel oil, whereas industry and agriculture contribute significantly to emissions to water and soil, respectively. By far the most important nickel-containing waste stream is domestic waste. In general the emissions are expected to decrease. NTIS

Previous work by other researchers suggest that the r-values measured from thick-gauge tantalum plate do not correspond to the predicted r-values calculated from ODF coefficients. To understand this behavior, bulk texture analysis using neutron diffraction techniques was conducted on annealed samples of Ta and Ta-2.5W plate: the pure tantalum exhibited a primary (111) type texture, whereas the alloy contained a cube texture. For the pure tantalum, the r-values calculated from the texture of as-annealed and the deformed specimens were similar and correlated well with measured data. The r-value of the Ta-2.5W exhibited a greater degree of strain-sensitivity, such that the calculated r-values based on the initial texture did not represent those calculated or measured after tensile deformation. Strain sensitivity of r-values in Ta and Ta-2.5W plates is related to the generation of a ((bar 1)10) fiber texture during deformation. DOE

CHARACTERIZATION OF THE MICROSTRUCTURE OF Nb-1WT.%Zr-0.1WT.%C TUBES AS AFFECTED BY THERMOMECHANICAL PROCESSING

Mehmet Uz (Lafayette Coll., Easton, PA.) and Robert H. Titran Dec. 1993 12 p Presented at the 11th Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 9-13 Jan. 1994 Sponsored by DOE
(Contract DE-2103-86SF-16310; RTOP 583-02-01)
(NASA-TM-106381; E-8194; NAS 1.15:106381; DOE/NASA/16310-21)
Avail: CASI HC A03/MF A01

Microstructure of Nb-1Zr-0.1C tubes were characterized as affected by extrusion temperature of the tube shell and its thermomechanical processing to tubing. Two tube shells of about 40-mm outside diameter (OD) and 25-mm inside diameter (ID) were extruded 8:1 from a vacuum arc-melted ingot at 1900 and 1550 K. Two different OD tubes of approximately 0.36-mm wall thickness were fabricated from each tube shell by a series of 26 cold drawing operations with two in process anneals. The microstructure of tube shells and the tubing before and after a 2-step heat treatment were characterized. Residue extracted chemically from each sample was also analyzed to identify the precipitates. The results concerning the effect of the initial extrusion temperature and subsequent processing on the microstructure of the tubes are presented together with a review of results from similar work on Nb-1Zr-0.1C sheet stock. The advanced regeneratively cooled rocket thrust chamber may require new materials to achieve long life and improved performance. Current materials such as NARloy-Z (Cu-3 wt. percent Ag-0.5 wt. percent Zr), while highly conductive, do not have sufficient high temperature strength and creep resistance to meet the projected needs of advanced rocket motors. A Cu-8 at. percent Cr-4 at. percent Nb (Cu-8 Cr-4 Nb) alloy has been identified as a promising material for this application. However, hydrogen embrittlement is a concern given the presence of high pressure, high temperature hydrogen in regeneratively cooled rocket motors. Thermodynamic analysis of the reaction between Cr-rich Cr2Nb and H2 showed that there is a possibility of reaction at temperatures up to 323 K in a 35 MPa H2 environment. Above 323 K the pressure necessary to achieve reaction rapidly increased beyond the range experienced in rocket motors. Tensile specimens exposed in 34.5 MPa H2 at room temperatures and during cycling to 705 C did not show any degradation of properties. No evidence of reaction was observed for Cr2Nb precipitate observed on the fracture surfaces. Based on these results the Cu-8 Cr-4 Nb alloy was judged to be sufficiently stable for use in rocket motors. Author (revised)

Using BFS, a new semiempirical method for alloys, we study the surface structure of fcc ordered binary alloys in the Ll(sub 2) structure (Ni3Al and Cu3Au). We show that the surface energy is lowest for the mixed composition truncation of the low-index faces of such systems. Also, we present results for the interlayer relaxations for planes close to the surface, revealing different relaxations for atoms of different species producing a rippled surface layer. MAGNETIC RESONANCE STUDIES OF 3D TRANSITION METAL IMPURITIES IN COMPOUND SEMICONDUCTORS Ph.D. Thesis

S. J. C. H. M. vanGisbergen 18 Feb. 1993 142 p See also DE89-609615 Sponsored by Stichting voor Fundamenteel Onderzoek der Materie, Amsterdam, Netherlands Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-232197) Avail: Issuing Activity (National Technical Information Service (NTIS))

In the thesis magnetic resonance is used to study transition element impurities with an electron configuration (Ar)3d(sup 5) (Mn(2+) and Fe(3+)) in compound semiconductors. The techniques employed are electron paramagnetic resonance (EPR); electron-nuclear double resonance (ENDOR), which combines EPR with nuclear magnetic resonance (NMR); and optically detected magnetic resonance (ODMR), in which detection of the EPR occurs via induced changes of a photoluminescence signal. The outline of the thesis is as follows: In chapter two an introduction is given to magnetic resonance and the experimental set-ups are described. In chapter three this is further specified for the case of 3d transition metal impurities in compound semiconductors. In chapter four the identification of interstitial Mn(2+) in GaAs and GaP by EPR is reported and in chapter five ENDOR measurements on substitutional Mn(2+) in GaAs are discussed. Chapter six deals with the observation of anomalous line intensities in the EPR spectrum of Fe(3+) in GaAs, for which electric quadrupole excitation effects are believed to be responsible. Finally, in chapter seven an ODMR study is performed on the diluted magnetic semiconductor Cd(0.905)Mn(0.095)Te. NTIS

THE STATISTICS OF SPUTTERING

M. T. Robinson 1993 14 p Presented at the ICACS 15th International Conference on Atomic Collision in Solids, London, Canada, 26-30 Jul. 1993
(Contract DE-AC05-84OR-21400)
(DE94-001128; CONF-930712-7) Avail: CASI HC A03/MF A01

The MARLOWE program was used to study the statistics of sputtering on the example of 1- to 100-keV Au atoms normally incident on static (001) and (111) Au crystals. The yield of sputtered atoms was examined as a function of the impact point of the incident particles ('ions') on the target surfaces. There were variations on two scales. The effects of the axial and planar channeling of the ions could be traced. The details depended upon the orientation of the target and the energies of the ions. Locally, the sputtering yield was very sensitive to the impact point, small changes in position often producing large changes yield. Results indicate strongly that the sputtering yield is a random ('chaotic') function of the impact point. DOE

STRENGTH, ACOUSTIC EVALUATION AND METALLURGY OF DIFFUSION BONDS

O. Buck and G. C. Ojard 1993 11 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-7405-eng-82)
(DE94-001804; IS-M-773; CONF-931009-6) Avail: CASI HC A03/MF A01

This paper discusses our efforts on two model systems to determine the bond strength, its correlation to acoustic NDE and the metallurgy involved in the process. Results indicate that the total acoustic energy, reflected from the original interface, can differentiate between the various bond strengths achieved. However, depending on types of materials to be joined, the atomistic processes, leading to a variety of microstructures in the bond planes, can become quite complex and strongly dominate the mechanical properties of such bonds. Origin of failure initiating defects is discussed. DOE

LARGE-SCALE PRODUCTION OF Si(0.8)Ge(0.2) THERMOELECTRIC ALLOYS BY MECHANICAL ALLOYING

B. A. Cook, J. L. Harringa, S. Loughin (Martin Marietta Astro Space, Philadelphia, PA.), and D. X. Centurioni (Martin Marietta Astro Space, Philadelphia, PA.) 1993 4 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993
(Contract W-7405-eng-82)
(DE94-000695; IS-M-767; CONF-930804-20) Avail: CASI HC A01/MF A01

Advanced processing techniques were combined with refinements in composition to produce homogeneous, production-scale quantities of n- and p-type Si(0.8)Ge(0.2) alloys with improved thermoelectric properties. Two p-type compacts of Si(0.8)Ge(0.2) doped with 0.8 atom% boron and one n-type compact doped with 0.8 m/o GaP and a P/Ga ratio of 2.38 were prepared by mechanical alloying. Resulting powders were consolidated into 7.62 cm diameter compacts by vacuum hot pressing. Transport and thermoelectric properties were measured. As-pressed samples were found to have low carrier mobility. Metallographic analysis revealed a sub-micron grain size which would suggest a high density of grain boundary potential barriers. A heat treatment was applied and the measurements were repeated. The post-treatment p-type samples showed a 33% grain growth and an integrated average figure of merit of 0.6 x 10(exp -3) K(exp -1) over the 573-1273 K range. This paper presents the details of fabrication method and compares the thermoelectric properties with the properties of similar alloys manufactured by traditional vacuum casting and hot pressing. DEVELOPMENT TESTING OF THE TWO-WATT RTG HEAT SOURCE AND HASTELLOY-S/T-111 ALLOY COMPATIBILITY STUDIES

E. I. Howell and P. E. Teaney 29 Sep. 1993 29 p
(Contract DE-AC04-88DP-43495)
(DE94-002875; MLM-3786) Avail: CASI HC A03/MF A01

The two-watt radioisotope thermoelectric generator heat source capsules were tested to determine their survivability under extreme environmental conditions: high external pressure, high impact, and high internal pressure. Test results showed that the capsules could withstand external pressures of 1,000 bars and impacts at velocities near 150 meters per second. However, the results of the internal pressure tests (stress-rupture) were not so favorable, possibly because of copper contamination, leading to a recommendation for additional testing. A material compatibility study examined the use of Hastelloy-S as a material to clad the tantalum strength member of the two-watt radioisotopic heat source. Test capsules were subjected to high temperatures for various lengths of time, then cross sectioned and examined with a scanning electron microscope. Results of the study indicate that Hastelloy-S would be compatible with the underlying alloy, not only at the normal operating temperatures of the heat source, but also when exposed to the much higher temperatures of a credible accident scenario. EFFECT OF IRRADIATION ON THE STRESS CORROSION CRACKING BEHAVIOR OF ALLOY X-750 AND ALLOY 625
W. J. Mills, M. R. Lebo, J. J. Kearns, R. C. Hoffman, J. J. Korinko, R. F. Luther, and G. B. Sykes 1993 10 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts DE-AC11-93PN38195; DE-AC11-89PN-38014)
(DE94-001759; WAPD-T-2990; CONF-930825-11) Avail: CASI HC A02

In-reactor testing of bolt-loaded precracked and as-notched compact tension specimens was performed in 360 C water to determine effect of irradiation on SCC of Condition HTH and Condition BH Alloy X-750 and age-hardened Alloy 625. Variables were stress intensity factor (K(sub I)) level, fluence, grade of HTH material, prestraining and material chemistry. Effects of irradiation on high temperature SCC and the rapid cracking that occurs during cooldown below 150 C were characterized. Significant degradation in the in-reactor SCC resistance of HTH material was observed at initial K(sub I) levels above 30 MPa(radical)m and fluences greater than 10(exp 19) n/sq cm (E greater than 1 MeV). A small degradation in SCC resistance of HTH material was observed at low fluences (less than 10(exp 16) n/sq cm). As-notched specimens displayed less degradation in SCC resistance than precracked specimens. Prestraining greatly improved in-flux and out-of-flux SCC resistance of HTH material, as little or no SCC was observed in precracked specimens prestrained 20 to 30%, whereas extensive cracking was observed in nonprestrained specimens. Condition HTH heats with low boron (10 ppM or less) had improved in-reactor SCC resistance compared to heats with high and intermediate boron (greater than 20 ppM). Age-hardened Alloy 625 exhibited superior in-reactor SCC behavior compared to HTH material as no crack extension occurred in any of the precracked Alloy 625 specimens tested at initial K(sub I) levels up to 80 MPa(radical)m. Mullite was reacted with pure Al and with Ti or Zr dissolved in Ag-Cu eutectic alloys at 1100 C in Ar. Analysis of the Ti and Zr-containing specimens showed reaction zones with compositions of Ti(50)Cu(30)O(20) and ZrO2, respectively. The Al-mullite specimen showed much more extensive penetration into the ceramic and a more diffuse reaction zone than the other two systems. Al2O3 and Si were the main reaction products for Al-mullite reaction. DOE

HOT HYDROGEN TESTING OF METALLIC TURBO PUMP MATERIALS Final Report, 13 May 1992 - 12 May 1993
Ralph Zee, Bryan Chin, and Rohit Inamdar 12 May 1993 80 p
(Contract NAS8-39131)
(NASA-CR-193880; NAS 1.26:193880) Avail: CASI HC A05/MF A01

The objectives of this investigation are to expose heat resistant alloys to hydrogen at elevated temperatures and to use various microstructural and analytical techniques to determine the chemical and rate process involved in degradation of these materials due to hydrogen environment. Inconel 718 and NASA-23 (wrought and cast) are candidate materials. The degradation of these materials in the presence of 1 to 5 atmospheric pressure of hydrogen from 450 C to 1100 C was examined. The hydrogen facility at Auburn University was used for this purpose. Control experiments were also conducted wherein the samples were exposed to vacuum so that a direct comparison of the results would separate the thermal contribution from the hydrogen effects. The samples were analyzed prior to and after exposure. A residual gas collection system was used to determine the gaseous species produced by any chemical reaction that may have occurred during the exposure. Analysis of this gas sample shows only the presence of H2 as expected. Analyses of the samples were conducted using optical microscopy, x-ray diffraction, scanning electron microscopy, and weight change. There appears to be no change in weight of the samples as a result of hydrogen exposure. In addition no visible change on the surface structure was detected. This indicates that the materials of interest do not have strong interaction with hot hydrogen. This is consistent with the microstructure results. Author (revised)

FEASIBILITY STUDY OF SHOT-PEENING MODELING
S. A. Meguid Mar. 1992 179 p
(CTN-94-60926) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

A review is presented of the state of the art in the field of shot peening to enhance fatigue life and inhibit stress corrosion cracking of aircraft structures, namely aluminum 2xxx and 7xxx series, high strength alloy steels 4xxx series and titanium alloys. The review examines the modeling of the process, the generation and relaxation of the resulting stress field, and their adequacy in interpreting the resulting fatigue life improvement of the treated parts. Attention is also devoted to the evaluation of peening residual stresses and their associated models. The fundamentals of shot peening are reviewed, the effect of residual stress on the fatigue fracture behavior of the above alloys is evaluated, and the effect of peening treatment on the stress corrosion cracking behavior of the materials of interest is assessed. The relaxation of the resulting residual stress field due to cyclic and thermal loadings is covered, and recommendations are made for future research. Author (CISTI)

SEGREGATION AND OXIDATION STUDIES OF AL-LI AND AL-MG ALLOYS Ph.D. Thesis
Frank Joseph Esposto Jun. 1993 152 p

(ISBN-0-315-83993-7; CTN-94-60959) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Auger electron spectroscopy, work function measurements, low energy electron diffraction, nuclear reaction analysis, dynamic/static secondary ion mass spectrometry, thermal desorption spectroscopy, and synchrotron radiation photoemission spectroscopy were used to investigate the segregation and oxidation of (111) oriented Al-6.5 percent Li and (110) oriented Al-1.45 percent Mg single crystal binary alloys. The resulting Li and Mg equilibrium surface concentrations are found to be 0.16 and 0.47 respectively. For both alloys, the increase in surface concentration was associated with a decrease in the change in work function. Ordered surface alloy phases were observed accompanying surface segregation with Al-Li and Al-Mg single crystal alloys. Oxidation measurements clearly indicate that the reactivities of the two alloy surfaces are substantially increased at the equilibrium Li and Mg surface concentrations. Oxidation of the Li-segregated surface occurs immediately, forming a mixed oxide composed of Al, Li, and O. The oxidation of the Mg-segregated surface also occurs immediately and leads to formation of a combination oxide (Al2O3 + MgO) at higher exposures. Author (CISTI)

PROCEDURES FOR DETERMINING MATMOD-4V MATERIAL CONSTANTS

T. C. Lowe 1993 17 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993

(Contract W-7405-eng-36)

(DE94-002638; LA-UR-93-3584; CONF-931121-29) Avail: CASI HC A03/MF A01

The MATMOD-4V constitutive relations were developed from the original MATMOD model to extend the range of nonelastic deformation behaviors represented to include transient phenomena such as strain softening. Improvements in MATMOD-4V increased the number of independent material constants and the difficulty in determining their values. Though the constitutive relations are conceptually simple, their form and procedures for obtaining their constants can be complex. This paper reviews in detail the experiments, numerical procedures, and assumptions that have been used to determine a complete set of MATMOD-4V constants for high purity aluminum. DOE

ENVIRONMENTALLY ASSISTED CRACKING OF HIGH STRENGTH BETA TITANIUM ALLOYS Annual Report, 15 Sep. 1992 - 15 Sep. 1993

Nov. 1993 118 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-91-J-4164)

(AD-A273598) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The objective of this integrated research program is to define the conditions under which high strength Beta-titanium alloys resist environmentally assisted cracking (EAC) in marine environments. Specific goals are to: (1) characterize EAC for metallurgical, chemical, and mechanical conditions that could destabilize crack tip passive films to promote local dissolution and hydrogen (H) uptake, (2) test the hydrogen embrittlement mechanism for EAC, and (3) develop a mechanism-based model of EAC by integrating crack chemistry, surface dissolution and repassivation kinetics, hydrogen uptake to trap sites, and crack tip process zone micromechanics and damage. The following conclusions were established in FY 93 based on rising load fracture mechanics experiments with solution treated and peak aged Ti-15-3 (15V-3Cr-3A1-3Sn; wt%) and Beta 21S (Ti- 15Mo-3Nb-3Al; wt%) in aqueous NaCl. This work is detailed in the attached paper. DTIC

SYMPOSIUM ON DIFFUSION IN ORDERED ALLOYS Final Report, 31 Mar. 1992 - 1 Jun. 1993

Brent Fulz 1 Jun. 1993 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-92-J-1921)

(AD-A273643) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Diffusion in ordered alloys and intermetallic compounds has received little attention in recent years, even though it lies at the heart of many fundamental and practical problems. As opposed to diffusion in dilute alloys or solid solutions, atom movements in ordered alloys are affected by the state of order in the material. Conversely, atom movements change the state of order, either locally, leading to large diffusional correlation factors, or globally, leading to order-disorder transformations. Diffusion controls the sequence of compound formation during the intermixing of pure elements, and affects properties such as creep, hydrogen embrittlement, and stability against electromigration. SURFACE COMPOSITIONAL VARIATIONS OF Mo-47Re ALLOY AS A FUNCTION OF TEMPERATURE

S. J. Hoekje (Analytical Services and Materials, Inc., Hampton, VA.), R. A. Outlaw, and S. N. Sankaran (Analytical Services and Materials, Inc., Hampton, VA.) Dec. 1993 31 p

(RTOP 763-23-45)

(NASA-TP-3402; L-17278; NAS 1.60:3402) Avail: CASI HC A03/MF A01

Molybdenum-rhenium alloys are candidate materials for the National Aero-Space Plane (NASP) as well as for other applications in generic hypersonics. These materials are expected to be subjected to high-temperature (above 1200 C) casual hydrogen (below 50 torr), which could potentially degrade the material strength. Since the uptake of hydrogen may be controlled by the contaminant surface barriers, a study of Mo-47Re was conducted to examine the variations in surface composition as a function of temperature from 25 C to 1000 C. Pure molybdenum and rhenium were also examined and the results compared with those for the alloy. The analytical techniques employed were Auger electron spectroscopy, electron energy loss spectroscopy, ion scattering spectroscopy, and x ray photoelectron spectroscopy. The native surface was rich in metallic oxides that disappeared at elevated temperatures. As the temperature increased, the carbon and oxygen disappeared by 800 C and the surface was subsequently populated by the segregation of silicon, presumably from the grain boundaries. The alloy readily chemisorbed oxygen, which disappeared with heating. The disappearance temperature progressively increased for successive dosings. When the alloy was exposed to 800 torr of hydrogen

at 900 C for 1 hour, no hydrogen interaction was observed.

(NASA-CR-4572; NAS 1.26:4572) Avail: CASI HC A04/MF A01

FRANC 2D (FRacture ANalysis Code, 2 Dimensions) is a menu driven, interactive finite element computer code that performs fracture mechanics analyses of 2-D structures. The code has an automatic mesh generator for triangular and quadrilateral elements. FRANC2D calculates the stress intensity factor using linear elastic fracture mechanics and evaluates crack extension using several methods that may be selected by the user. The code features a mesh refinement and adaptive mesh generation capability that is automatically developed according to the predicted crack extension direction and length. The code also has unique features that permit the analysis of layered structure with load transfer through simulated mechanical fasteners or bonded joints. The code was written for UNIX workstations with X-windows graphics and may be executed on the following computers: DEC DecStation 3000 and 5000 series, IBM RS/6000 series, Hewlitt-Packard 9000/700 series, SUN Sparc stations, and most Silicon Graphics models.

WORKSHOP ON THE THERMOPHYSICAL PROPERTIES OF MOLTEN MATERIALS
Nov. 1993 247 p Workshop held in Cleveland, OH, 22-23 Oct. 1992
(RTOP 674-27-05)
(NASA-CP-10121; E-8069; NAS 1.55:10121) Avail: CASI HC A11/MF A03

The role of accurate thermophysical property data in the process design and modeling of solidification processes was the subject of a workshop held on 22-23 Oct. 1992 in Cleveland, Ohio. The workshop was divided into three sequential sessions dealing with (1) industrial needs and priorities for thermophysical data, (2) experimental capabilities for measuring the necessary data, and (3) theoretical capabilities for predicting the necessary data. In addition, a 2-hour panel discussion of the salient issues was featured as well as a 2-hour caucus that assessed priorities and identified action plans. For individual titles, see N94-25121 through N94-25135.

THE IMPORTANCE OF PROPERTIES IN MODELING
A. F. Giamei *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 15-29
(For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

Casting and welding of superalloys, stainless steel and titanium alloys are processes which can be improved through modeling of heat flow, fluid flow, residual stress development, and microstructural evolution. These simulations require inputs of thermophysical data, some of which involves the partially or totally liquid state. In particular, these processes involve melting, flow in the liquid, and solidification. Modeling of such processes can lead to an improved understanding of defects such as shrinkage, inclusions, cracks, incomplete filling (or penetration), macrosegregation, improper grain structure, and deviations from dimensional specifications. Effective modeling can shorten process development time and improve quality. An approach to these problems is to develop efficient models; validate through correlations with thermal, distortion, and microstructural data; run parametric studies; extract knowledge based rules; and apply to adaptive closed loop control systems. With the appropriate pre- and post-processing, such analyses can be made 'user friendly'. This would include graphical user interfaces as well as realistic images and color maps. In such form, these models can be used for sensitivity analyses, which are useful in defining appropriate sensors and in the development of control strategies. Such modeling can be done at several levels, e.g., the MARO level, modeling large scale phenomena such as heat and fluid flow or material deformation; the MICRO level, modeling the development of dendrites, grains or precipitates; or at the NANO level, modeling point defects, dislocations, stacking faults, etc. There are many computational issues associated with these simulations, e.g. computational efficiency and accuracy. In addition, there are many materials issues, not the least of which is the availability of accurate high temperature thermophysical data for complex alloys. This would include latent heat of fusion, temperature dependent heat capacity and thermal conductivity (for liquid and solid), viscosity, surface tension, thermal expansion, mechanical properties, etc. Preliminary data is frequently gathered from the literature; however, this is often not available for modern alloys. If additional data are required, measurements can be used; however, these are costly, time consuming and can be erroneous due to a lack of testing standards or impure materials. Microstructural predictors can be extracted from thermal information, e.g. cooling rate and thermal gradient; the prediction of microstructure is dependent on solidus and liquidus temperature, mushy zone permeability, the solidification curve, volume changes, phase transformations, alloying effects (such as surface tension or viscosity), mold/metal reactions, metal/environment reactions, etc. Defect maps may be needed to predict the onset of shrinkage, hot cracking or 'freckling'. Constants may be needed for stress relaxation, dendrite coarsening, vaporization, etc. Visualization was used as a tool to better comprehend complex data sets associated with the analysis of directional solidification (including crystal growth) and welding. Examples include not only isotherms, but also cooling rate, growth rate and thermal gradient. The latter two are not single valued scalars, but rather time and space dependent vector fields. Efficient models were developed for both casting and welding to predict heat flow and the relationship to dendrite and grain growth. These codes include many of the non-linear effects, e.g. radiation, which dominate these processes. The home-built FDM code(s) were designed to be useful not only to the scientist, but also to the process engineer. Special output can be requested to compare directly to experimental data. Visualization procedures were developed to visualize critical results, e.g. fusion zone width at the surface opposite that where the arc is applied ('penetration'). Both elaborate and simplified distortion analyses were carried out. It is clear that extensive mechanical property data are critical in order to accurately predict residual stress patterns. A scheme is currently being developed to integrate these modeling tools into a set of control algorithms; however, the success of this approach is critically dependent on the availability of accurate high temperature thermophysical data.

THERMOPHYSICAL PROPERTY SENSITIVITY EFFECTS IN STEEL SOLIDIFICATION
Tony Overfelt *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 35-50
(For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

The simulation of advanced solidification processes via digital computer techniques has gained widespread acceptance during the last decade or so. Models today can predict transient temperature fields, fluid flow fields, important microstructural parameters, and potential defects in castings. However, the lack of accurate thermophysical property data on important industrial alloys threatens to limit the ability of manufacturers to fully capitalize on the technology's benefits. A study of the sensitivity of one such numerical model of a steel plate casting to imposed variations in the data utilized for the thermal conductivity, specific heat, density, and heat of fusion is described. The sensitivity of the data's variability is characterized by its effects on the net solidification time of various points along the centerline of the plate casting. Recommendations for property measurements are given and the implications of data uncertainty for modelers are discussed.

The Center for Information and Numerical Data Analysis and Synthesis, (CINDAS), measures and maintains databases on thermophysical, thermoradiative, mechanical, optical, electronic, ablation, and physical properties of materials. Emphasis is on aerospace structural materials especially composites and on infrared detector/sensor materials. Within CINDAS, the Department of Defense sponsors at Purdue several centers: the High Temperature Material Information Analysis Center (HTMIAC), the Ceramics Information Analysis Center (CIAC) and the Metals Information Analysis Center (MIAC). The responsibilities of CINDAS are extremely broad encompassing basic and applied research, measurement of the properties of thin wires and thin foils as well as bulk materials, acquisition and search of world-wide literature, critical evaluation of data, generation of estimated values to fill data voids, investigation of constitutive, structural, processing, environmental, and rapid heating and loading effects, and dissemination of data. Liquids, gases, molten materials and solids are all considered. The responsibility of maintaining widely used databases includes data evaluation, analysis, correlation, and synthesis. Material property data recorded on the literature are often conflicting, diverging, and subject to large uncertainties. It is admittedly difficult to accurately measure materials properties. Systematic and random errors both enter. Some errors result from lack of characterization of the material itself (impurity effects). In some cases assumed boundary conditions corresponding to a theoretical model are not obtained in the experiments. Stray heat flows and losses must be accounted for. Some experimental methods are inappropriate and in other cases appropriate methods are carried out with poor technique. Conflicts in data may be resolved by curve fitting of the data to theoretical or empirical models or correlation in terms of various affecting parameters. Reasons (e.g. phase transitions) must be found for unusual dependence or any anomaly. Such critical evaluation involves knowledge of theory, experience in measurement, familiarity with metallurgy (microstructural behavior) and not inconsiderable judgment. An examination of typical data compiled and analyzed by CINDAS shows that the thermal conductivity of a material reported in the literature may vary by a factor of two of more; the range of reported values increases as temperature increases reflecting the difficulty of high temperature measurements. Often only estimates of melt behavior are available, despite the importance of melt properties in modeling, welding, or other solidification processes. There may be only a few measurements available for properties such as kinematic viscosity, even for widely used materials such as stainless steel. In the face of such a paucity of existing data and in a national environment where too few new data are being generated it is nonetheless the responsibility of CINDAS to select and disseminate recommended values of a wide variety of thermophysical properties. DYNAMIC MEASUREMENTS OF THERMOPHYSICAL PROPERTIES OF METALS AND ALLOYS AT HIGH TEMPERATURES BY SUBSECOND PULSE HEATING TECHNIQUES

Ared Cezairliyan *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 71-85
(For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

Rapid (subsecond) heating techniques developed at the National Institute of Standards and Technology for the measurements of selected thermophysical and related properties of metals and alloys at high temperatures (above 1000 C) are described. The techniques are based on rapid resistive self-heating of the specimen from room temperature to the desired high temperature in short times and measuring the relevant experimental quantities, such as electrical current through the specimen, voltage across the specimen, specimen temperature, length, etc., with appropriate time resolution. The first technique, referred to as the millisecond-resolution technique, is for measurements on solid metals and alloys in the temperature range 1000 C to the melting temperature of the specimen. It utilizes a heavy battery bank for the energy source, and the total heating time of the specimen is typically in the range of 100-1000 ms. Data are recorded digitally every 0.5 ms with a full-scale resolution of about one part in 8000. The properties that can be measured with this system are as follows: specific heat, enthalpy, thermal expansion, electrical resistivity, normal spectral emissivity, hemispherical total emissivity, temperature and energy of solid-solid phase transformations, and melting temperature (solidus). The second technique, referred to as the microsecond-resolution technique, is for measurements on liquid metals and alloys in the temperature range 1200 to 6000 C. It utilizes a capacitor bank for the energy source, and the total heating time of the specimen is typically in the range 50-500 micro-s. Data are recorded digitally every 0.5 micro-s with a full-scale resolution of about one part in 4000. The properties that can be measured with this system are: melting temperature (solidus and liquidus), heat of fusion, specific heat, enthalpy, and electrical resistivity. The third technique is for measurements of the surface tension of liquid metals and alloys at their melting temperature. It utilizes a modified millisecond-resolution heating system designed for use in a microgravity environment. Author (revised)

CONTAINERLESS MEASUREMENTS ON LIQUIDS AT HIGH TEMPERATURES c25

Richard Weber *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 87-98
(For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

The application of containerless techniques for measurements of the thermophysical properties of high temperature liquids is reviewed. Recent results obtained in the materials research laboratories at Intersonics are also presented. Work to measure high temperature liquid properties is motivated by both the need for reliable property data for modeling of industrial processes involving molten materials and generation of data form basic modeling of materials behavior. The motivation for this work and examples of variations in thermophysical property values from the literature are presented. The variations may be attributed to changes in the specimen properties caused by chemical changes in the specimen and/or to measurement errors. The two methods used to achieve containerless conditions were aeroacoustic levitation and electromagnetic levitation. Their qualities are presented. The accompanying slides show the layout of levitation equipment and present examples of levitated metallic and ceramic specimens. Containerless techniques provide a high degree of control over specimen chemistry, nucleation and allow precise control of liquid composition to be achieved. Effects of minor additions can thus be measured in a systematic way. Operation in reduced gravity enables enhanced control of liquid motion which can allow measurement of liquid transport properties. Examples of nucleation control, the thermodynamics of oxide contamination removal, and control of the chromium content of liquid aluminum oxide by high temperature containerless processes are presented. The feasibility of measuring temperature, emissivity, liquidus temperature, enthalpy, surface tension, density, viscosity, and thermal diffusivity are discussed in the final section of the paper. LIQUIDUS TEMPERATURE AND OPTICAL PROPERTIES MEASUREMENT BY CONTAINERLESS TECHNIQUES

Collin D. Anderson *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 99-111
(For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

Reactive alloy liquidus temperatures measured by conventional, contained techniques are often in error due to reactions with containers and gaseous impurities. This paper describes a new liquidus temperature measurement technique that avoids these problems by employing containerless processing. This technique relies on precise and accurate noncontact temperature measurements (NCTM), which are made possible by spectral emissivity values. The spectral emissivities, epsilon(sub lambda), are measured along with the optical properties (real, n, and imaginary, k, components of the index of refraction) using polarimetric techniques on electromagnetically levitated specimens. Results from work done at Vanderbilt University and Intersonics on the Ti-Al system are presented to demonstrate the above techniques. Author (revised)

DETECTION OF VELOCITY IN HIGH TEMPERATURE LIQUID METALS

A. C. Mikrovas and S. A. Argyropoulos *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 113-127 (For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

Various efforts have been made to measure velocity in liquid metals. All of these efforts, however, share the same inherent limitation, namely, not being operative at the high temperatures required by liquid metals and liquid slags in an industrial application. In this paper, the current methods used were reviewed, and a new technique was presented for the measurement of velocity in high temperature liquid metals. In using this technique there are two stages. Starting with the calibration stage and then moving to the actual measurement stage by making use of the data obtained from calibration stage. Calibration proceeds in the following manner. Metallic spheres moving with a specific velocity are immersed in liquid metal held under isothermal conditions and at specific temperature. Their melting times are determined very accurately with a novel technique. These measurements are repeated for different metal bath temperatures and for different velocities of metallic spheres. In this manner it is possible to calculate the correlation between velocity and melting times for each metal bath temperature. During the actual measurement stage, when the metal bath temperature is known and its velocity is unknown, the magnitude of the unknown liquid metal velocity can be derived as follows: metallic spheres are immersed into the moving liquid metal and their melting times are determined. Using the above mentioned correlations, it will be shown that the magnitude of the unknown velocity in liquid metal can be deduced. This new technique was applied to high temperature liquid aluminum and liquid steel and these results were presented. The potential applicability of this technique in other liquid metals and liquid slags will also be discussed. Author (revised)

AN OVERVIEW OF THE MEASUREMENTS OF THERMOPHYSICAL PROPERTIES AND SOME RESULTS ON MOLTEN SUPERALLOYS AND SEMICONDUCTORS

R. E. Taylor *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 129-141 (For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

This presentation consists of two parts: comments on the results of measurements on thermophysical properties based on the paper, 'Things Mother Never Taught Me (About Thermophysical Properties of Solids)' and results of thermophysical property measurements on selected solid and molten semiconductors and a proprietary superalloy. The first part may be considered as a tutorial for those involved in using or procuring thermophysical property data. The second part is presented as illustrations of what has been accomplished on molten materials at the Thermophysical Properties Research Laboratory (TPRL). The materials include Ge, PbTe, PbSnTe, HgCdTe and a superalloy. Derived from text

OPTICAL PROPERTIES AND EMISSIVITIES OF LIQUID METALS AND ALLOYS

Shankar Krishnan and Paul C. Nordine *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 143-160 (For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

This paper presents the results from our on-going program to investigate the optical properties of liquid metals and alloys at elevated temperatures. Ellipsometric and polarimetric techniques have been used to investigate the optical properties of materials in the 1000 - 3000 K temperature range and in the 0.3 - 0.1 mu m wavelength range. The ellipsometric and polarimetric techniques are described and the characteristics of the instruments are presented. The measurements are conducted by reflecting a polarized laser beam from an electromagnetically levitated liquid metal or alloy specimen. A Rotating Analyzer Ellipsometer (RAE) or a four-detector Division-of-Amplitude Photopolarimeter (DOAP) is used to determine the polarimetric properties of the light reflected at an angle of incidence of approximately 68 deg. Optical properties of the specimen which are calculated from these measurements include the index of refraction, extinction coefficient, normal spectral emissivity, and spectral hemispherical emissivity. These properties have been determined at various wavelengths and temperatures for liquid Ag, Al, Au, Cu, Nb, Ni, Pd, Pt, Si, Ti, Ti-Al alloys, U, and Zr. We also describe new experiments using pulsed-dye laser spectroscopic ellipsometry for studies of the wavelength dependence of the emissivities and optical properties of materials at high temperature. Preliminary results are given for liquid Al. The application of four-detector polarimetry for rapid determination of surface emissivity and true temperature is also described. Characteristics of these devices are presented. An example of the accuracy of this instrument in measurements of the melting point of zirconium is illustrated. Author

THERMOPHYSICAL PROPERTIES OF SIMPLE LIQUID METALS: A BRIEF REVIEW OF THEORY

David Stroud *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 163-176 (For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

In this paper, we review the current theory of the thermophysical properties of simple liquid metals. The emphasis is on thermodynamic properties, but we also briefly discuss the nonequilibrium properties of liquid metals. We begin by defining a 'simple liquid metal' as one in which the valence electrons interact only weakly with the ionic cores, so that the interaction can be treated by perturbation theory. We then write down the equilibrium Hamiltonian of a liquid metal as a sum of five terms: the bare ion-ion interaction, the electron-electron interaction, the bare electron-ion interaction, and the kinetic energies of electrons and ions. Since the electron-ion interaction can be treated by perturbation, the electronic part contributes in two ways to the Helmholtz free energy: it gives a density-dependent term which is independent of the arrangement of ions, and it acts to screen the ion-ion interaction, giving rise to effective ion-ion pair potentials which are density-dependent, in general. After sketching the form of a typical pair potential, we briefly enumerate some methods for calculating the ionic distribution function and hence the Helmholtz free energy of the liquid: monte Carlo simulations, molecular dynamics simulations, and thermodynamic perturbation theory. The final result is a general expression for the Helmholtz free energy of the liquid metal. It can be used to calculate a wide range of thermodynamic properties of simple metal liquids, which we enumerate. They include not only a range of thermodynamic coefficients of both metals and alloys, but also many aspects of the phase diagram, including freezing curves of pure elements and phase diagrams of liquid alloys (including liquidus and solidus curves). We briefly mention some key discoveries resulting from previous applications of this method, and point out that the same methods work for other materials not normally considered to be liquid metals (such as colloidal suspensions, in which the suspended microspheres behave like ions screened by the salt solution in which they are suspended). We conclude with a brief discussion of some non-equilibrium (i.e., transport) properties which can be treated by an extension of these methods. These include electrical resistivity, thermal conductivity, viscosity, atomic self-diffusion coefficients, concentration diffusion coefficients in alloys, surface tension and thermal emissivity. Finally, we briefly mention two methods by which the theory might be extended to non-simple liquid metals: these are empirical techniques (i.e., empirical two- and three-body potentials), and numerical many-body approaches. Both may be potentially applicable to extremely complex systems, such as nonstoichiometric liquid semiconductor alloys. Author

A THERMODYNAMIC APPROACH TO OBTAIN MATERIALS PROPERTIES FOR ENGINEERING APPLICATIONS

Y. Austin Chang *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 177-201 (For primary document see N94-25120 06-26)
Avail: CASI HC A03/MF A03

With the ever increases in the capabilities of computers for numerical computations, we are on the verge of using these tools to model manufacturing processes for improving the efficiency of these processes as well as the quality of the products. One such process is casting for the production of metals. However, in order to model metal casting processes in a meaningful way it is essential to have the basic properties of these materials in their molten state, solid state as well as in the mixed state of solid and liquid. Some of the properties needed may be considered as intrinsic such as the density, heat capacity or enthalpy of freezing of a pure metal, while others are not. For instance, the enthalpy of solidification of an alloy is not a defined thermodynamic quantity. Its value depends on the micro-segregation of the phases during the course of solidification.

The objective of the present study is to present a thermodynamic approach to obtain some of the intrinsic properties and combining thermodynamics with kinetic models to estimate such quantities as the enthalpy of solidification of an alloy. Derived from text

AN EXTENDED LASER FLASH TECHNIQUE FOR THERMAL DIFFUSIVITY MEASUREMENT OF HIGH-TEMPERATURE MATERIALS c25
F. Shen and J. M. Khodadadi *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 203-218 (For primary document see N94-25120 06-26)
(Grant NAGw-1192)
Avail: CASI HC A03/MF A03

Knowledge of thermal diffusivity data for high-temperature materials (solids and liquids) is very important in analyzing a number of processes, among them solidification, crystal growth, and welding. However, reliable thermal diffusivity versus temperature data, particularly those for high-temperature liquids, are still far from complete. The main measurement difficulties are due to the presence of convection and the requirement for a container. Fortunately, the availability of levitation techniques has made it possible to solve the containment problem. Based on the feasibility of the levitation technology, a new laser flash technique which is applicable to both levitated liquid and solid samples is being developed. At this point, the analysis for solid samples is near completion and highlights of the technique are presented here. The levitated solid sample which is assumed to be a sphere is subjected to a very short burst of high power radiant energy. The temperature of the irradiated surface area is elevated and a transient heat transfer process takes place within the sample. This containerless process is a two-dimensional unsteady heat conduction problem. Due to the nonlinearity of the radiative plus convective boundary condition, an analytic solution cannot be obtained. Two options are available at this point. Firstly, the radiation boundary condition can be linearized, which then accommodates a closed-form analytic solution. Comparison of the analytic curves for the temperature rise at different points to the experimentally-measured values will then provide the thermal diffusivity values. Secondly, one may set up an inverse conduction problem whereby experimentally obtained surface temperature history is used as the boundary conditions. The thermal diffusivity can then be elevated by minimizing the difference between the real heat flux boundary condition (radiation plus convection) and the measurements. Status of an experimental study directed at measuring the thermal diffusivity of high-temperature solid samples of pure Nickel and Inconel 718 superalloys are presented. Preliminary measurements showing surface temperature histories are discussed. Author

Avail: CASI HC A02/MF A03

The fundamental surface chemistry of the behavior of liquid metals spreading on a solid substrate is not at all well understood. Each of these questions involves knowing the details of the structure of interfaces and their dynamics. For example the structure of a monolayer of tin oxide on pure liquid tin is unknown. This is in contrast to the relatively large amount of data available on the structure of copper oxide monolayers on solid, pure copper. However, since liquid tin has a vapor pressure below 10(exp -10)torr for a reasonable temperature range above its melting point, it is possible to use the techniques of surface science to study the geometric, electronic and vibrational structures of these monolayers. In addition, certain techniques developed by surface chemists for the study of liquid systems can be applied to the ultra-high vacuum environment. In particular we have shown that light scattering spectroscopy can be used to study the surface tension tensor of these interfaces. The tin oxide layer in particular is very interesting in that the monolayer is rigid but admits of bending. Ellipsometric microscopy allows the visualization of monolayer thick films and show whether island formation occurs at various levels of dosing. Author

MICROWAVE TECHNIQUES FOR PHYSICAL PROPERTY MEASUREMENTS c25
M. Barmatz *In* NASA. Lewis Research Center, Workshop on the Thermophysical Properties of Molten Materials Nov. 1993 p 231-234 (For primary document see N94-25120 06-26)
Avail: CASI HC A01/MF A03

Industrial processing of metals and ceramics is now being streamlined by the development of theoretical models. High temperature thermophysical properties of these materials are required to successfully apply these theories. Unfortunately, there is insufficient experimental data available for many of these properties, particularly in the molten state. Microwave fields can be used to measure specific heat, thermal diffusivity, thermal conductivity and dielectric constants at high temperatures. We propose to (1) develop a microwave flash method (analogous to the laser flash technique) that can simultaneously measure the thermal diffusivity and specific heat of insulators and semiconductors at high temperatures, (2) an appropriate theory and experimental apparatus to demonstrate the measurement of the specific heat of a metal using a new microwave ac specific heat technique, and (3) experimental methods for noncontact measurement of the real and imaginary dielectric constants. Measurements of thermophysical properties of undercooled liquids often require some kind of levitator which isolates samples from container walls. We introduce in this presentation a high temperature/high vacuum electrostatic levitator (HTHVESL) which promises some unique capabilities for the studies of thermophysical properties of molten materials. Although substantial progress has been made in the past several months, this technology is still in the development stage, therefore, in this presentation we only focus on the present state of the HTHVESL(1) and point out other capabilities which might be realized in the near future. X RAY DIFFRACTION ANALYSIS OF ELECTRODEPOSITED BETA-TANTALUM Final Report
John F. Thompson and Mark D. Miller Sep. 1993 21 p
(AD-A273254; ARCCB-TR-93031) Avail: CASI HC A03/MF A01

An adherent coating of beta-tantalum has been electrodeposited on copper from a FLINAK molten salt electrolyte. Electrolyte temperatures ranged from 700 to 800 C using pulse current electrolysis at current densities higher than 100 mA/sq cm. The beta-tantalum was deposited to a thickness of over 3 mils. The x ray diffraction pattern of the electrodeposited beta-tantalum was indexed using a Hull-Davey chart. The coatings were found to have a highly preferred orientation, and the tetragonal structure was found to have the lattice parameters of a = 6.419 A and c = 3.051 A. DTIC

Equivalent crystal theory (ECT) is applied to the study of multilayer relaxations and surface energies of high-index faces of Fe, Al, Ni, and Cu. Changes in interplanar spacing as well as registry of planes close to the surface and the ensuing surface energies changes are discussed in reference to available experimental data and other theoretical calculations. Since ECT is a semiempirical method, the dependence of the results on the variation of the input used was investigated. Author (revised)

SOLID STATE SYNTHESIS OF Fe-B-SI ALLOYS
Pekka Ruuskanen and Oleg Heczko Oct. 1992 34 p Sponsored by Technical Research Centre of Finland, Espoo; Stroemberg Industry/Automation, Vaasa, Finland; Rauma Oy High Speed Technology, Finland; and Trafotek Oy, Finland
(VTT-PUBS-118; ISBN-9-51-384236-5; ETN-94-95234) Copyright Avail: CASI HC A03/MF A01

Fe-B and Fe-B-Si elemental and intermetallic powders were synthesized by the mechanical alloying method. Vibratory and planetary type of ball mills were used. The alloying time and the alloying type in the results were investigated. The microstructure and the thermodymaic properties of the mechanically alloyed powders were characterized. X-ray diffractometry differential scanning calorimetry and a scanning electron microscopy were applied. The results show that it is possible to synthesize nanocrystalline and amorphous alloys from elemental and intermetallic Fe, B, and Si powders with the iron content of 80 percent. The crystallization temperature of the amorphous structure is 465 C. The measured magnetic properties suggest that in this way it is possible to produce new kinds of soft magnetic materials. The magnetic hysteresis properties of the compacted rings made from the mechanically alloyed Fe-B and Fe-B-Si powders were measured. ESA

(VTT-TIED-1416; ISBN-9-51-384310-6; ETN-94-95255) Copyright Avail: CASI HC A03/MF A01

A study on the use of the Scanning Tunneling Microscope (STM) in corrosion research is reported. Using an STM it is possible to study the surfaces of metals in the circumstances where they are used. The measurements can be made in vacuum, gases--including air, and in liquids. When considering the simultaneous use of electrochemical measurements and STM, some development of designs and methods is still needed so that the tunneling current would not disturb the electrochemical current and vice versa. Some interesting issues to study with STM could be the dissolving of a metal on an atomistic scale, the location of anode areas during corrosion, and the time constants associated with them. Other practicable areas of applications in the field of corrosion could, among others, be the study of initiation and growth of pitting and the adsorption of aggressive anions and/or inhibitors on the metal surfaces. WELDABILITY OF ACCELERATED-COOLED (AcC) HIGH STRENGTH TMCP STEEL X80
Pekka Nevasmaa, Mark Cederberg, and Martti Vilpas Oct. 1992 41 p
Sponsored by Nordic Industrial Fund; Technology Development Center, Finland; and Technical Research Centre of Finland, Espoo
(VTT-TIED-1413; ISBN-951-38-4307-6; ETN-94-95254) Copyright Avail: CASI HC A03/MF A01

The test results obtained in welding and weldability tests of an Accelerated Cooled (AcC) Thermochemically Processed (TMCP) X80 pipeline steel are discussed. The tests comprised mechanical testing of joints welded with arc energies ranging from 15 to 50 kJ/cm using Submerged Arc Welding (SAW) and Flux Cored Arc Welding (FCAW) processes. The results of weld thermal simulation and implant weldability tests for the steel are reported and discussed. The results demonstrate the improved weldability of the AcC X80 steel, as compared to normalized or quenched and tempered steels of a similar strength level. Welding without preheat was possible up to 15 to 25 mm plate thickness using arc energies of 10 and 22 kJ/cm, respectively. No weld metal cracking was observed in the heat input range studied in this X80 class, although welding was performed without preheat. The welded joints failed to meet the toughness requirements all through the arc energy range from 15 to 50 kJ/cm. Adequate hardness measurement of impact toughness was obtained only in one of the joints welded with a low arc energy of 15 kJ/cm. The Charpy 5 tests of simulated hardness measurements confirmed a deterioration in toughness at -40 C through the whole cooling time range t(sub 8/5) of 12 to 52 sec. Charpy 5 test data from real hardness measurements suggested that some improvement could be expected at temperatures of -20 C, when limiting the maximum allowable heat input below 15 kJ/cm. ESA

The potentialities of Disilane in the production of Low Pressure Chemical Vapor Deposition (LPCVD) of polysilicon films are investigated. The purpose is to characterize the effects of deposition parameters on the film kinetics, homogeneity, crystallization, and oxidation at 600 C. The physicochemical phenomena occurring during deposition steps, which justify the homogeneity as well as the kinetic characteristics of the films obtained, are investigated. The 600 C neutral atmosphere annealing results show that Disilane allows the obtention of optimal crystallization and maximal oxidation films. The electric properties of thin film transistors are characterized. ESA

GAS-PRESSURE FORMING OF SUPERPLASTIC CERAMIC SHEET

T. G. Nieh and J. Wadsworth 24 Jun. 1993 4 p
(Contract W-7405-eng-48)
(DE94-001520; UCRL-CR-114189) Avail: CASI HC A01/MF A01

Superplasticity in ceramics has now advanced to the stage that technologically viable superplastic deformation processing can be performed. In this paper, examples of biaxial gas-pressure forming of several ceramics are given. These include yttria stabilized, tetragonal zirconia (YTZP), a 20% alumina/YTZP composite, and silicon. In addition, the concurrent superplastic forming and diffusion bonding of a hybrid YTZP/C103 (ceramic-metal) structure are presented. These forming processes offer technological advantages of greater dimensional control and increased variety and complexity of shapes than is possible with conventional ceramic shaping technology. (DE94-001528; UCRL-JC-114192; CONF-9308158-3) Avail: CASI HC A03/MF A01

Aerogels are unique porous materials whose composition, structure, and properties can be controlled at the nanometer scale. This paper examines the synthesis of organic aerogels and their carbonized derivatives. Carbon aerogels have low electrical resistivity, high surface area, and a tunable pore size. These materials are finding applications as electrodes in double layer capacitors. DOE

THE STRUCTURE AND SPIN DYNAMICS OF LANTHANIDE-BEARING SILICATE GLASSES

A. J. G. Ellison, C. K. Loong, and J. Wagner 1993 13 p Presented at the 38th Annual Conference on Magnetism and Magnetic Materials, Minneapolis, MN, 15-18 Nov. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE94-001320; ANL/IPNS/CP-79847; CONF-931133-4) Avail: CASI HC A03

Structures of 3Na2O(center dot)R2O3(center dot)6SiO2 (R = Nd, Yb and Lu) glasses were studied by time-of-flight neutron diffraction. Average Si-O and O-O nearest-neighbor coordination is found to be similar to SiO4 tetrahedral units in vitreous SiO2 and other silicate glasses. The RE ions coordinate with no more than 7 nearest-neighbor oxygen atoms. The dynamic and static response of these glasses and their isochemical crystalline analogs have been investigated by inelastic neutron scattering and magnetic susceptibility measurements. The magnetic excitation spectra were analyzed by a ligand-field model using a method of descending symmetry. Correlation between short-range atomic order in a network glass and magnetic interactions of the RE ions with the local environment is discussed. DOE

The di(hydroxyphenyl)- 1,2,4-triazole monomers were first synthesized by reacting bis (4-hydroxyphenyl) hydrazide with aniline hydrochloride at 250 C in the melt and also by reacting 1,3 or 1,4-bis- (4-hydroxyphenyl)-phenylene- dihydrazide with 2 moles of aniline hydrochloride in the melt. Purification of the di(hydroxyphenyl)- 1,2,4-triazole monomers was accomplished by recrystallization. Poly (1,2,4-triazoles) (PT) were prepared by the aromatic nucleophilic displacement reaction of di(hydroxyphenyl)-1,2,4-triazole monomers with activated aromatic dihalides or activated aromatic dinitro compounds. The reactions were carried out in polar aprotic solvents such as sulfolane or diphenylsulfone using alkali metal bases such as potassium carbonate at elevated temperatures under nitrogen. This synthetic route has provided high molecular weight PT of new chemical structure, is economically and synthetically more favorable than other routes, and allows for facile chemical structure variation due to the availability of a large variety of activated aromatic dihalides.

An aqueous process was developed to prepare a consolidated composite laminate from an aqueous slurry. An aqueous poly(amic acid) surfactant solution was prepared by dissolving a poly(amic acid) powder in an aqueous ammonia solution. A polymeric powder was added to this solution to form a slurry. The slurry was deposited on carbon fiber to form a prepreg which was dried and stacked to form a composite laminate. The composite laminate was consolidated using pressure and was heated to form the polymeric matrix. The resulting composite laminate exhibited high fracture toughness and excellent consolidation.

A process for preparing polyimides having enhanced melt flow properties is described. The process consists of heating a mixture of a high molecular weight poly-(amic acid) or polyimide with a low molecular weight amic acid or imide additive in the range of 0.05 to 15 percent by weight of the additive. The polyimide powders so obtained show improved processability, as evidenced by lower melt viscosity by capillary rheometry. Likewise, films prepared from mixtures of polymers with additives show improved processability with earlier onset of stretching by TMA.

A NUMERICAL ANALYSIS OF CRACK PROPAGATION IN MICROCRACKING CERAMIC AND CERAMIC COMPOSITES

S. B. Biner 1993 24 p Presented at the 1st Meeting of the Pacific Rim Ceramic Societies, Honolulu, HI, 7-10 Nov. 1993
(Contract W-7405-eng-82)
(DE94-001192; IS-M-771; CONF-931142-1) Avail: CASI HC A03/MF A01

A set of numerical analyses of crack growth was performed to elucidate the mechanism of microcracking on the observed fracture behavior of ceramics and ceramic composites. The random nucleation, orientation and size effects of discrete microcracks and resulting interactions are fully accounted for in a hybrid finite element model. The results indicate that the energy expenditure due the microcrack nucleation seems not to contribute significantly to the resistance to crack growth. The main controlling parameter appears to be elastic interaction of the microcracks with the main crack in the absence of a reinforcing phase; therefore, the microcrack density plays an important role. In the case of the composites, the interaction of the main crack with the stress fields of the reinforcing phase, rather than interaction of microcracks, is the controlling parameter for the resistance to the crack growth even in the presence of a large population of microcracks. It will be also shown that the crack branching and crack kinking can readily develop as a result of microcracking. DOE

Di(hydroxyphenyl)benzimidazole monomers were prepared from phenyl-hydroxybenzoate and aromatic bis(o-diamine)s. These monomers were used in the synthesis of soluble polybenzimidazoles. The reaction involved the aromatic nucleophilic displacement of various di(hydroxyphenyl)benzimidazole monomers with activated aromatic dihalides or activated aromatic dinitro compounds in the presence of an alkali metal base. These polymers exhibited lower glass transition temperatures, improved solubility, and better compression moldability over their commercial counterparts. US-Patent-Class-264-DIG.19; Int-Patent-Class-C04B-35/52) Avail: US Patent and Trademark Office

Novel high strength ceramic fibers derived from boron, silicon, and carbon organic precursor polymers are discussed. The ceramic fibers are thermally stable up to and beyond 1200 C in air. The method of preparation of the boron-silicon-carbon fibers from a low oxygen content organosilicon boron precursor polymer of the general formula Si(R2)BR(sup 1) includes melt-spinning, crosslinking, and pyrolysis. Specifically, the crosslinked (or cured) precursor organic polymer fibers do not melt or deform during pyrolysis to form the silicon-boron-carbon ceramic fiber. These novel silicon-boron-carbon ceramic fibers are useful in high temperature applications because they retain tensile and other properties up to 1200 C, from 1200 to 1300 C, and in some cases higher than 1300 C.

Tests of the burn characteristics of a phenolic foam, under evaluation as runway brake arrestor material, were conducted by the Fire Safety Branch of the Federal Aviation Administration (FAA) Technical Center. The purpose of these tests was to assess the fire propagation properties of phenolic foam when exposed to a free burning Jet A fuel fire and to determine the fire control time of phenolic foam immersed in a jet fuel fire when extinguished using three-percent aqueous film forming foam (AFFF). Three pool fire tests were conducted as follows: In the first and second tests, a 12-foot-square bed of phenolic foam material was placed adjacent to a 35-foot diameter jet fuel fire. This configuration resulted in ignition and flame propagation across to adjacent foam material, resulting in charring of over 30 percent of the exposed surface of the phenolic foam. In the third test, the phenolic foam material was immersed in the jet fuel fire to determine ease of extinguishment using conventional AFFF agent. The fire control time was three times longer than when the phenolic foam material was absent. The extinguishing time was an order of magnitude higher than that without the foam. In addition, the phenolic foam material was evaluated on the basis of FAA fire test requirements for cabin material. These small-scale tests measured burn length, weight loss, and heat release rate of the foam material in accordance with Federal Aviation Regulation (FAR) 25.853. These results showed the foam material passed the burn test requirements. Author (revised)

Infrared transmission was employed to study the formation of a lubricating film deposited on two different substrates at 700 C. The deposit was formed from tricresylphosphate vapors and collected onto a NaCl substrate and on an iron coated NaCl substrate. Analysis of the infrared data suggests that a metal phosphate is formed initially, followed by the formation of organophosphorus polymeric compounds. Author (revised)

SELECTIVE HYDROGEN SEPARATION BY PALLADIUM-BASED COMPOSITE MEMBRANES

E. Aksnes, I. Dahl, and A. Stori (Center for Industrial Research, Oslo, Norway.) 10 Feb. 1993 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB93-201671; STF28-A93013) Avail: Issuing Activity (National Technical Information Service (NTIS))

Composite Pd/Ag polymer membranes for selective hydrogen permeation have been made. Experiments show that there is good adhesion between plasma sputtered Pd/Ag films and polysulphone. With 30/70 (weight) Ag/Pd films room temperature stable metal films with thicknesses of less than 0.2 micrometers can be made. Even films with a thickness of 0.02 micrometers acted as an efficient barrier for an inert gas like N_2. The thinner films were the most stable towards mechanical and chemical stresses induced by cycling the hydrogen pressure. NTIS

(RTOP 233-01-01)

(NASA-TM-107751; NAS 1.15:107751) Avail: CASI HC A04/MF A01

This memorandum presents an introduction to the NASA multi-purpose prepregging unit which is now installed and fully operational at the Langley Research Center in the Polymeric Materials Branch. A description of the various impregnation methods that are available to the prepregger are presented. Machine operating details and protocol are provided for its various modes of operation. These include, where appropriate, the related equations for predicting the desired prepreg specifications. Also, as the prepregger is modular in its construction, each individual section is described and discussed. Safety concerns are an important factor and a chapter has been included that highlights the major safety features. Initial experiences and observations for fiber impregnation are described. These first observations have given great insight into the areas of future work that need to be addressed. Future memorandums will focus on these individual processes and their related problems. SURFACE AND INTERFACIAL PROPERTIES OF POLYMER BLENDS. A LITERATURE SURVEY

M. Hiljanen, M. Heino, R. Holsti-Miettinen, J. Seppaelae, and J. Sjoeblom Mar. 1993 85 p Sponsored by Nordisk Industrifond Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB93-230191; ISBN-951-22-1449-0) Avail: Issuing Activity (National Technical Information Service (NTIS))

The commercial development of polymer alloys and blends has had a rapid growth in importance during the 1980's. For example, in 1987, it was estimated that 60 to 70% of polyolefins and 23% of other polymers were sold as blends. In the literature survey emphasis is put on the surface/interfacial properties of the blend components and of the final product. The reason for such a literature approach is that these properties are of extreme importance for final morphologies, and, hence they must be studied. The report gives a broad survey of different experimental techniques for determination of surface/interfacial energies. NTIS

COMBUSTION SYNTHESIS AND ENGINEERING OF NANOPARTICLES FOR ELECTRONIC, STRUCTURAL AND SUPERCONDUCTOR APPLICATIONS

G. C. Stangle, V. R. W. Amarakoon, and W. A. Schulze 19 Aug. 1993 23 p

(Contract DE-FG02-93ER-12128)

(DE94-001865; DOE/ER-12128/2) Avail: CASI HC A03/MF A01

Fully dense, nanocrystalline ceramic articles were prepared by a new nanofabrication process. The process consists of two steps: synthesis of ceramic nanoparticles and fabrication of dense, nanocrystalline ceramic parts. The synthesis step produced 10-nanometer diameter crystallites, and is capable of being scaled up to kilogram/hour production rates. The fabrication step produced dense parts at significantly reduced sintering temperatures and times, representing a factor of 10-100 reduction in process energy requirements. Process was demonstrated by producing ultrafine-grained yttria-stabilized ZrO_2, an important material with a variety of energy-related applications (e.g., solid electrolytes, oxygen sensors, electrode materials, thermal barrier coatings, etc.). Results from this period illustrate capabilities of this energy-efficient and directly commercializable process for producing dense, nanocrystalline, multicomponent oxide ceramics. DOE

DEVELOPMENT OF A THEORY OF THE WEAR OF CERAMICS

R. S. Cowan (Georgia Inst. of Tech., Atlanta.) and W. O. Winer (Georgia Inst. of Tech., Atlanta.) Oct. 1993 108 p

(Contract DE-AC05-84OR-21400)

(DE94-002773; ORNL/Sub-93-07802) Avail: CASI HC A06/MF A02

The objective of this program was to develop a theory to predict wear behavior of lubricated and unlubricated ceramics in sliding contact, and present it in a form useful for designers. It is assumed that the contact between bodies in sliding motion produces a stress field and frictional heat source that may induce severe wear from material yielding or fracture. A thermomechanical wear model is used to develop a wear transition equation for identifying the dominant factors that will reduce or control such wear by employing thermoelasticity analyses and contact mechanics. This equation is used to construct wear maps for ease of analysis. Studies are devoted to substantiating the thermomechanical wear model by using experimental results that emphasize the transition from mild to severe wear for dry and lubricated metallic and ceramic sliding contacts under load. A glass-ceramic composition is provided, comprising mainly SiO_2, Al_2O_3, and Li_2O and/or MgO. The composition is obtained by preparing a gel by hydrolysis and poly condensation of precursor metal compounds in solution in a solvent, removing the solvent, grinding the gel if required, and finally dehydrating and oxidizing the gel followed by compaction and ceramization by increasing the temperature. The precursors used are preferably silicon alcoholates and aluminum alcoholates, more particularly tetraethyl ortho silicate and aluminum sec butoxide, and inorganic compounds of Li and/or Mg. It has been found that the glass-ceramic composition is substantially in the form of solid ceramic solutions having a low expansion coefficient. This and other properties favor formation of fiber reinforced composites with good thermomechanical characteristics. To obtain a fiber reinforced composite with a refractory ceramic matrix, the fibers can be incorporated in the powder of the glass-ceramic composition before the compacting heat treatment. This procedure is particularly applied to SiC-based fibers. When these fibers contain an appreciable amount of oxygen and carbon on the surface, the composition preferably also contains at least one additional component such as Nb2O5 to limit adhesion of the composition to the fibers. INTRODUCTION OF CERAMICS INTO AEROSPACE STRUCTURAL COMPOSITES [L'INTRODUCTION DES CERAMIQUES DANS LES COMPOSITES UTILISES DANS LES STRUCTURES DES SYSTEMES AEROSPATIAUX]

Nov. 1993 160 p In ENGLISH and FRENCH Workshop held in Antalya, Turkey, 21-22 Apr. 1993
(AGARD-R-795; ISBN-92-835-0728-2) Copyright Avail: CASI HC A08/MF A02

Ceramics have been considered over the last two decades as a possible alternative to refractory metals and alloys to be used as structural materials for aeronautical use. The main disadvantage of these materials is their brittleness and the very low value of the critical size of defects leading to fracture. The concept of ceramic matrix composites has been recognized as one of the ways to escape this difficulty. Extensive work has been performed to identify the mechanisms of crack propagation and general fracture for unidirectional composites, laminates or other fabrics, including the understanding of their long term response: creep and fatigue effects or environmental degradation. The Workshop which has been held by AGARD SMP at Antalya (Turkey), April 1993, aimed at reviewing the present knowledge on all these aspects. For individual titles, see N94-24229 through N94-24240.

During the last decade, Ceramic Matrix Composites (CMC) have undergone a rapid development, and today, quite a number of composites are available. SiC/SiC and C/SiC, processed by Chemical Vapor Infiltration (CVI), are now produced on an industrial scale. C/SiC composites can currently operate at temperatures above 1600 C for propulsion applications on launchers and missiles. Other composites with oxide or silicon-nitride matrices are under development. The processing routes are moving from CVI to more cost-effective processes such as sol-gel and polymer precursor. These routes appear very promising since they currently use the technologies already developed for Organic Matrix Composites and carbon-carbon composites. The real challenge for these materials is in the areas of the working temperature, which must exceed 1600C, and the environmental behavior. To meet these requirements, new fibers with an increased thermal stability are under development. Author (revised)

A methodology for the straightforward and consistent evaluation of the constituent properties of CMC's is summarized. The methodology is based on an analyses of current literature. The results provide a constitutive law capable of simulating the stress/strain behavior of these materials. The approach is illustrated using data for two CMC's: SiC/CAS and SiC/SiC. The constituent properties are also used as input to mechanics procedures that characterize stress redistribution and predict the effect of strain concentrations on macroscopic performance. Author

The results of pushout tests on two ceramic matrix composites are presented and discussed. Emphasis is placed on the effect of interface roughness on the interfacial properties. Toward that end, techniques used to characterize fiber and interface topography are described and results presented. An advanced analysis, which takes account of the roughness contribution to the radial stress during debonding, is used to calculate interfacial properties. It is observed that the fiber fabrication technique has a profound effect on the nature of the interfacial topography. Author

MICROMECHANICAL FAILURE MODES IN BRITTLE MATRIX COMPOSITES

Ceramic-and glass ceramic matrix composites are being touted for application in high temperature structural components. Before their potential can be realized, however, understanding of the significance of the fracture modes that occur at very low stress levels well beneath those commonly assumed to initiate microcracking in the literature, will be essential. Unfortunately, at this point in the technology development, the precise definition of these mechanisms, i.e., the geography of the fracture plane(s), has been described rather incompletely in experimental research. In most cases, the experimental observations only provide views of these cracks at their intersection with a surface of the composite. Thus, in this presentation, we will provide some predictions of failure scenarios based upon a hypothetical idealized initial flaw in the matrix-an annular crack in a plane normal to the fibers of an unidirectional composite. Although many of the properties needed for the modeling study have not been realistically determined, especially the in-situ strength/ fracture properties, and the fracture criteria itself incorporates an undetermined parameter, i.e., initial flaw size, it is hoped that the modeling can serve to determine the nature of the parameters that require measurement and to help establish the sensitivity of the response to these parameters, as well as to guide experimental efforts to attempt validation of the failure processes hypothesized. The complexity of these processes seems to demand an iterative approach between the analyst and experimentalist. Derived from text

The paper describes the potential of micromechanical studies using the instrumented Vickers indentation test in force and displacement. For ceramics reinforced by long fibers, it is possible to determine the hardness and the elastic modulus of the components as well as the mechanical characteristics of the fiber-matrix interface. Oxide and covalent (silicon carbide) matrix composites reinforced by SiC-Nicalon fibers are considered as examples. Author

ROLE OF INTERFACES ON THE CYCLIC FATIGUE BEHAVIOUR OF CERAMIC MATRIX COMPOSITES

D. Rouby and P. Reynaud *In* AGARD, Introduction of Ceramics into Aerospace Structural Composites Nov. 1993 10 p Sponsored by CNRS; Ministere de la Recherche et de l'Espace; Direction des Recherches, Etudes et Techniques; and CNES (For primary document see N94-24228 06-27)

Copyright Avail: CASI HC A02/MF A02

Ceramics reinforced with continuous fibers exhibit delayed failure under pulsating load. A micromechanical model describing the fatigue effects is proposed. It is based on the decreasing of the shear stress at the fiber-matrix interfaces, resulting from interfacial wear due to the see-saw sliding. The main features of this model are the following: during first loading cycle, the material exhibits multiple matrix cracking and some fiber breaks. During subsequent cycles, the interfacial shear stress decreases, leading to increasing the failure probability of the bridging fibers. For a critical fraction of broken bridging fibers, instability occurs and the specimen fails, thus, defining the lifetime. For lower peak stresses, but higher still than the proportionality limit, the material also evolves but no failure occurs (up to one million cycles), indicating that the interfacial shear stress decreases to a non-zero lower bound. Fatigue induced changes of interfacial shear stress are also observed from fiber pull-out length analyses. Author

MECHANICAL BEHAVIOR OF CMCs: CRACK GROWTH RESISTANCE AND CREEP ASPECTS

M. Gomina and J. L. Chermant *In* AGARD, Introduction of Ceramics into Aerospace Structural Composites Nov. 1993 18 p (For primary document see N94-24228 06-27)

Copyright Avail: CASI HC A03/MF A02

Rupture and creep behavior of ceramic matrix composites (CMC's) are discussed. The influence of the specimen geometry and size on the R-curve behavior for two types of SiC/C/SiC composite materials were investigated. The experimental results obtained using in-situ matrix crack lengths indicate that the shape of the resistance curve depends essentially on the predominant toughening mechanism (extensive matrix microcracking or fiber-matrix debonding) whereas the frontal process zone size is the same for both types of materials. K(sub R)-Delta(a) curves of SENB and small CT specimens rise as a consequence of the ligament which cannot contain the fully developed frontal process zone. Using large CT specimens, a minimum ligament size necessary to contain the frontal process zone and thus a K(sub R)-Delta(a) behavior free of structure size is observed. Creep results obtained using three point bending tests are also presented for these materials and for SiC-MLAS materials. Author (revised)

MICROSTRUCTURE AND MICROMECHANICAL BEHAVIOUR OF CMCs

M. H. Lewis, A. Chamberlain, A. M. Daniel, M. W. Pharaoh, A. G. Razzell, and S. Sutherland *In* AGARD, Introduction of Ceramics into Aerospace Structural Composites Nov. 1993 13 p Sponsored by Science Research Council and Rolls Royce Ltd. (For primary document see N94-24228 06-27)

Copyright Avail: CASI HC A03/MF A02

A survey is presented of research aimed at an understanding of the relation between microstructure, interface properties, and macromechanical behavior of a range of silicate (glass ceramic) and nitride matrix composites. For silicate ceramic matrix composites (CMC's), hot-pressing cycle (P/T) in relation to matrix chemistry and fiber type is critical in avoiding mechanical and chemical damage of fibers with consequent reduction in ultimate CMC strength. Interfacial debond and shear stresses, measured via a fiber 'push-down' indentation technique exhibit a wide variation, dependent on CMC processing time, temperature and matrix chemistry and thermal expansion. 'Graceful' failure, typified by 3 stage stress-strain curves, may be obtained for debond energies Gamma and shear stresses tau up to approximately 20 Jm(sup -2) and approximately 50 MPa, respectively. Interface-oxidation-induced property degradation occurs at intermediate temperatures (400-800 C) but is suppressed at higher temperatures by passive oxidation of SiC fiber ends which prevents further carbon interface removal by channeled reaction. Higher temperature SiC (Textron CVD) monofilament based CMC's with Si3N4 (SRBSN) matrices were fabricated using tape-cast matrix preforms. Partially sacrificial C-coatings on the monofilaments provide low Gamma and tau interfaces and result in ideal composite response with separation between matrix cracking stress and ultimate stress, followed by filament pull-out. Although interface oxidation is a limiting problem for creep and stress rupture, these properties are superior to turbine superalloys. Author (revised)

CERAMIC MATRIX COMPOSITE PARTS DESIGN

P. Lamicq and D. Boury *In* AGARD, Introduction of Ceramics into Aerospace Structural Composites Nov. 1993 12 p (For primary document see N94-24228 06-27)

Copyright Avail: CASI HC A03/MF A02

Ceramic matrix composites (CMC) are making up a new material family that presents a significant potential for thermostructure design. They show a good specific strength and stiffness up to high temperatures and these characteristics are associated to non-fragile behaviors which do correspond to the designer practical requirements. After a short description of the CMC most used by SEP designers, a thought on part design and dimensioning with these materials is presented. An approach of the currently used general methodology is presented, followed by various comments specific to the use of these materials. Finally, some examples of singular behaviors, which are currently poorly controlled by simple modeling and require advanced rupture criteria, are given. Derived from text

CMC DESIGN CONSEQUENCES

W. Krenkel *In* AGARD, Introduction of Ceramics into Aerospace Structural Composites Nov. 1993 12 p (For primary document see N94-24228 06-27)

Copyright Avail: CASI HC A03/MF A02

Ceramic matrix composites (CMC) have widely demonstrated their feasibility and performance although no series production has been achieved. Today's status is characterized by long production times, high material qualities with high reproducibility and experience in the first structural components. Some unsolved problems are the joining and attachment of CMC parts, the lack of adequate nondestructive testing methods and the insufficient oxidative stability for long term applications. This paper deals with general valid design aspects as a consequence of the CMC materials characteristics and the demand for structural components of high reliability. Author

INTEGRATED APPROACH IN MODELLING, TESTING, AND DESIGN OF GRADIENT-CVI DERIVED CMC COMPONENTS

D. Sygulla, A. Muehlratzer, and P. Agatonovic *In* AGARD, Introduction of Ceramics into Aerospace Structural Composites Nov. 1993 13 p Sponsored by BMFT (For primary document see N94-24228 06-27)

Copyright Avail: CASI HC A03/MF A02

Ceramic composite materials with continuous fibers in a SIC matrix, manufactured by CVI, have shown benefits for structural applications due to high fracture toughness and damage tolerance under operational conditions. However, the production time associated with the hitherto applied CVI technique entails development cycles of hardly acceptable long duration. Therefore, there is growing interest for the CVI technique to manufacture reliable CMC parts, focusing special attention on a more efficient production technology. In this paper a current attempt to develop and qualify a new CVI process, the so-called gradient-CVI, is described and discussed. This process offers increased productivity appropriate for industrial production and excellent material properties. Author

This paper outlines new concepts for the utilization of various ultrasonic techniques for the evaluation of different aspects of development and use of ceramic matrix composites. We introduce a novel mechanical parameter called the interfacial shear stiffness coefficient which can be measured using ultrasonic shear wave reflectivity technique to characterize and quantify the fiber-matrix interface. This newly proposed parameter is promising as a common basis of composite evaluation among the composites developing, composites mechanics modeling and composites testing groups. The paper will also discuss other ultrasonic NDE techniques such as ultrasonic microscopy which can provide comprehensive evaluation of the composite system during all phases of development and use. STRUCTURAL CHARACTERIZATION AND THERMAL CYCLING BEHAVIOUR OF EB-PVD THERMAL BARRIER COATING SYSTEMS M.S. Thesis

Aline Faure-Geors 1993 85 p
(ISBN-0-315-83365-3; CTN-94-60958) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The behavior of thermal barrier coatings (TBC) produced by electron beam physical vapor deposition was investigated. Emphasis was placed on NiCoCrAlY type bond TBC. The effect of substrate temperature and ion beam assistance condition was first studied for top-coat free samples. Thermal cyclic tests of the samples were performed between 1,035 C and ambient temperature. Scanning electron microscopy and x-ray spectroscopic analyses conducted on the cross section showed the effect of ion beam assistance on modification of the composition profile of each element in as-deposited samples, which results in low Al content in the as-deposited bond coat and growth of a Cr-rich phase during thermal cycles. Samples with ceramic overlay were similarly studied. It was found that interdiffusion of alloying elements with the substrate and diffusion toward the oxide scale modified the bond coat composition and generated phase transformations or segregations, affecting the physical and/or mechanical properties of the bond coat and becoming involved in the degradation mechanism of the TBC. Raman spectroscopy showed that the predominant phase in ZrO2 having 7-10 weight percent of Y2O3 is tetragonal. This phase does not undergo the damaging transformation to monoclinic under the thermal cycling conditions studied. Preliminary work on compositionally graded TBC was also conducted. Author (CISTI)

SYNTHESIS OF SOLUBLE HALOGENATED POLYPHENYLENES: MECHANISM FOR THE COUPLING HALOGENATED LITHIOBENZENES

Eric B. Stephens, Kenneth E. Kinsey, Joanna F. Davis, and James M. Tour 22 Nov. 1993 28 p
(Contract N00014-89-J-3062)
(AD-A273547; TR-23) Avail: CASI HC A03/MF A01

A method for the synthesis of soluble polyphenylenes that involves the polymerization of 1-halo-4-lithiobenzenes, 1-halo-3-lithiobenzenes, and 1,3- and 1,4-dilithiobenzenes in ethereal solvents is described. The lithiobenzenes are prepared from the corresponding dihalogenated benzenes using tert-butyllithium. By varying the monomers and conditions used, a variety of soluble halogenated polyphenylenes can be obtained with weight average molecular weights (Mw) as high as 6,000 with polydispersities (Mw/Mn) equal to approximately 2.8. The pre-quenched polymers can exist as multi-lithiated polymers if 2.0 equivalents of tert-butyllithium are used to form the aryllithium intermediates. The polymers are usually amorphous and contain significant amounts of phenylated polyphenylene units capped with halogens. The polymers are soluble in organic solvents such as THF, chloroform, and methylene chloride. Several of the polymers exhibited low melting and glass transition temperatures. The brominated polymers are easily dehalogenated upon treatment with tert-butyllithium in THF at -78 C followed by quenching with water. The molecular weights of several of the brominated polymers increased upon debromination with tert-butyllithium. When the polymerizations were carried out in the presence of 1,3-diphenylisobenzofuran, ortho-benzyne intermediates were trapped as their Diels-Alder adducts. LiH appears to be present in significant amounts upon completion of the polymerization. DTIC

STM investigations were carried out on monolayers of poly(o-pentadecyl aniline), o-pentadecyl aniline monomer, and p-hexadecyl aniline. The polymer was prepared by Langmuir polymerization on a 0.1 M H2SO4 sub phase, containing ammonium persulfate as the oxidizing agent. Monolayers of all the compounds were transferred by the LB technique from the air/liquid interface to a MoS2 substrate. After annealing, molecular resolution images were obtained for all three compounds. The o-pentadecyl aniline monomer showed a decreased mean molecular area on the MoS2 surface, compared to that at the liquid/air interface, while the polymer images showed similar packing at both interfaces. The p-hexadecyl aniline showed similar ordering on the substrate as the ortho substituted monomer. The polymer images showed evidence of backbone connectivity. After annealing all monolayers showed high positional and orientational order. DTIC

NANODESIGNING OF HIERARCHICAL MULTIFUNCTIONAL CERAMICS Final Report, 1 Oct. 1990 - 31 Dec. 1992

Ilhan A. Aksay, M. Sarikaya, and D. M. Dabbs 28 Sep. 1993 36 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0040-91)
(AD-A273466; AFOSR-93-0670TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Methods of processing nanometer scale ceramics for use in structural and optoelectronic applications have been developed. Colloidal processing of fine scale ceramic powders was used because such an approach represents the most feasible processing methodology for the production of large scale devices and components. The project consists of two primary task areas: (1) fundamental studies in synthesis and processing; and (2) the processing and properties of ceramic matrix composites. For task one, the emphasis has been on the basic science of the synthesis and use of nanometer size particles. Task two, on the other hand, has been on the application of colloidal methods to the production of ceramic matrix composites for use in engineering applications. This project began at the University of Washington and was continued at Princeton University. DTIC

DURABILITY EVALUATION OF CERAMIC COMPONENTS USING CARES/LIFE

Noel N. Nemeth, Lynn M. Powers (Cleveland State Univ., OH.), Lesley A. Janosik, and John P. Gyekenyesi Jan. 1994 15 p Proposed for presentation at the 39th International Gas Turbine and Aeroengine Congress, The Hague, The Netherlands, 13-16 Jun. 1994; sponsored by ASME
(NASA-TM-106475; E-8402; NAS 1.15:106475) Avail: CASI HC A03/MF A01

The computer program CARES/LIFE calculates the time-dependent reliability of monolithic ceramic components subjected to thermomechanical and/or proof test loading. This program is an extension of the CARES (Ceramics Analysis and Reliability Evaluation of Structures) computer program. CARES/LIFE accounts for the phenomenon of subcritical crack growth (SCG) by utilizing the power law, Paris law, or Walker equation. The two-parameter Weibull cumulative distribution function is used to characterize the variation in component strength. The effects of multiaxial stresses are modeled using either the principle of independent action (PIA), the Weibull normal stress averaging method (NSA), or the Batdorf theory. Inert strength and fatigue parameters are estimated from rupture strength data of naturally flawed specimens loaded in static, dynamic, or cyclic fatigue. Application of this design methodology is demonstrated using experimental data from alumina bar and disk flexure specimens which exhibit SCG when exposed to water. Author

MOLTEN SALT REACTOR FOR POTENTIOSTATIC ELECTROPLATING Patent

Kurt H. Stern, inventor (to Navy) and Ralph M. Hess, inventor (to Navy) 7 Sep. 1993 7 p Filed 12 Mar. 1992 Supersedes AD-D015358
(AD-D016020; US-Patent-5,242,563; US-Patent-Appl-SN-850107; US-Patent-Class-204-241) Avail: US Patent and Trademark Office

A molten salt reactor for potentiostatic electroplating that includes a reactor chamber defined by a peripheral wall, a bottom wall, and a top cover is described. The bottom wall of the reactor chamber has an opening, to which a first end of a gas inlet conduit is attached so as to be in fluid communication with the reactor chamber. A crucible support platform is positioned within the reactor chamber, and a crucible for holding a molten salt is mounted thereon. A furnace substantially surrounds the peripheral wall of the reactor chamber and the first end of the gas inlet conduit. The crucible support platform is electrically insulated from the reactor chamber. An inert gas flows from the gas inlet conduit, through a lower portion of the reactor chamber, past the crucible support platform, through an upper portion of the reactor chamber, and to a gas outlet in the upper portion of the reactor chamber. The inert gas is heated within the first end of the gas inlet conduit prior to flowing into the lower portion of the reaction chamber. DTIC

CURING PHTHALONITRILE RESINS WITH ACID AND AMINE Patent

Peter J. Burchill, inventor (to Navy) and Teddy M. Keller, inventor (to Navy) 17 Aug. 1993 6 p Filed 9 Jan. 1992
(AD-D016021; US-Patent-5,237,045; US-Patent-Appl-SN-818575; US-Patent-Class-528-362) Avail: US Patent and Trademark Office

Polymerization of cure of di-phthalonitrile monomers or prepolymers by a curing agent selected from (1) an acid and amine, (2) a salt of an acid and an amine, and (3) mixtures of (1) and (2). In a preferred embodiment, the curing agents are amine salts which are reaction products of an aromatic amine and an aromatic sulfonic acid. The use of the curing agents enhances curing rates and results in polymers which have high T(sub g). DTIC

DIPOLAR RELAXATION IN A SECOND-ORDER NONLINEAR OPTICAL INTERPENETRATING POLYMER NETWORK Technical Report

J. I. Chen, S. Marturunkakul, L. Li, R. J. Jeng, and J. Kumar 29 Nov. 1993 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1148)
(AD-A273626; TR-94-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The nature of the relaxation process of the poled order in an inter-penetrating polymer network (IPN) system is found to be fundamentally different from that of a guest/host system. The IPN (Tg= 176 C) consists of a nonlinear optical (NLO) active epoxy-based polymer network and an NLO active phenoxy-silicon polymer network. The decay behavior of the second-order nonlinearity of this IPN was investigated in the range from 110 to 170 C. The stability of this IPN is superior to those of classic guest/host polymers as indicated by longer relaxation times at temperatures from 110 to 130 C. The relaxation process of the IPN system follows Arrhenius type behavior at temperatures ranging from 140 to 170 C. The IPN system provides a new approach to processing for stabilization of the second-order nonlinear optical properties. DTIC

N94-24737 Department of the Navy, Washington, DC.

HIGH TEMPERATURE ADHESIVE Patent

Teddy M. Keller, inventor (to Navy) and Charles M. Roland, inventor (to Navy) 7 Sep. 1993 7 p Filed 26 Feb. 1992 Supersedes AD-D015286
(AD-D016019; US-Patent-5,242,755; US-Patent-Appl-SN-841945; US-Patent-Class-428-457) Avail: US Patent and Trademark Office

A substrate assembly and method for its preparation, said substrate assembly comprising at least two substrates adhesively bonded with a cured thermosetting polymer being able to withstand a temperature of 200-400 C, is disclosed. The polymer is derived from a diphthalonitrile monomer and/or prepolymer with an aromatic moiety in the bridging group which monomer and/or prepolymer is solid at room temperature but which is rendered liquid by heating it to above its melting temperature. Said monomer in liquid state, and its prepolymer in liquid state, have tack with respect to said substrate. DTIC

ROBOTIC WELD OVERLAY COATINGS FOR EROSION CONTROL

B. F. Levin, J. N. Dupont, and A. R. Marder 20 Jul. 1993 28 p
(Contract DE-FG22-92PC-92542)
(DE94-002665; DOE/PC-92542/T3) Avail: CASI HC A03/MF A01

Twelve weld overlay hardfacing alloys have been selected for preliminary erosion testing based upon a literature review. Four of the selected coatings were deposited on a 1018 steel substrate using plasma arc welding process. During the past quarter, the remaining eight coatings were deposited in the same manner. Ten samples from each coating were prepared for erosion testing. Microstructural characterization of each coating is in progress. This progress report describes coating deposition and sample preparation procedures. Relation between coating hardness and formation of cracks in coatings is discussed. DOE

DEVELOPMENT OF HIGH TEMPERATURE LIQUID LUBRICANTS FOR LOW-HEAT REJECTION: HEAVY DUTY DIESEL ENGINES

P. D. Wiczynski and T. A. Marolewski Mar. 1993 77 p
(Contracts DEN3-373; DE-AI01-91CE-50306; RTOP 778-34-2A)
(NASA-CR-191197; NAS 1.26:191197; DOE/NASA/0373-1) Avail: CASI HC A05/MF A01

The objective of this DOE program was to develop a liquid lubricant that will allow advanced diesel engines to operate at top ring reversal temperatures approaching 500 C and sump temperatures approaching 250 C. The lubricants developed demonstrated at marginal increase in sump temperature capability, approximately 15 C, and an increase in top ring reversal temperature. A 15W-40 synthetic lubricant designated HTL-4 was the best lubricant developed in terms of stability, wear control, deposit control dispersancy, and particulate emissions. Author (revised)

ULTRASTRUCTURE PROCESSING OF MACROMOLECULAR MATERIALS Final Report, 12 Feb. 1990 - 11 Feb. 1993

Frank E. Karasz 25 Jun. 1993 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-90-C-0019)
(AD-A273413; AFOSR-93-0864TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The effect of microstructure on miscibility of polymer blends has been investigated in a number of model systems by thermal, mechanical, and novel spectroscopic techniques. An understanding of the fundamental basis of the metastable miscibility found in large number of high temperature systems, i.e. these typically involving polyimides or related materials with high Tg's has also been gained. In a complementary investigation, we have performed computer simulation studies of the equilibrium behavior of various blends, and under several types of constraint, to provide insights into behavior in binary systems at the segmental level. This study also investigated dynamic aspects, including phase separation. In another investigation, we have studied electro-optically active conjugated polymers, principally poly(p-phenylene vinylene) and its derivatives, modifications and blends. The emphasis has been on gaining a detailed understanding of the structural properties and concurrently exploiting the several electro-optical effects for which these polymer systems are noted. These include nonlinear optical phenomena and electroluminescence. Certain solution properties of polymer systems have also been studied. We have continued to use quasi-elastic light-scattering measurements to investigate translational diffusion of solvated polymers in porous media and other properties of polar and non-polar macromolecules. A synthetic effort in side-chain liquid crystal polymers has led to the systematic study of the thermal, mechanical and dielectric properties of several representation series and of their mixtures. CENTER FOR ADVANCED ELECTRICAL AND STRUCTURAL POLYMERS Final Report, 1 Mar. 1990 - 28 Feb. 1993

Frank E. Karasz 15 Oct. 1993 78 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Grant AF-AFOSR-0150-90)

(AD-A273415; AFOSR-93-0866TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Research in the U.R.I. has been organized into five thrust areas each comprising collateral and coordinated investigations in three departments at the University of Mass. and at Wright State University, Foster Miller Inc. and MIT. Electrical properties of pi-conjugated polymers are the focus of one thrust and are defined in terms of their structure-property relationships as well as long term applications. A prototypical polymer has been poly-p-phenylene vinylene. A second thrust has concentrated on nonlinear optical effects in pi-conjugated and side chain liquid crystal polymers containing chromophoric mesogens which have been synthesized and characterized, as have low-molecular weight model compounds of systematically varying structure. The third thrust has focused on polymer blends and alloys including high temperature novel processible systems for application in extreme conditions. Miscibility studies in conventional model polymers has continued to yield insights into the fundamental principles underlying polymer-polymer interactions. A computer simulation project has complemented these studies. The thrust on novel macromolecular architecture and characterization has produced a range of new systems and techniques including measurements of polymer dynamics in constricted geometries, and detailed fine-structure investigations of block copolymers. A thrust on new processing technologies has largely centered on the FMI initiatives with respect to novel approaches for high temperature polymer blend melts. DTIC

ULTRASONIC PROCESS FOR CURING ADHESIVES Interim Report, Jun. 1992 - Feb. 1993

Naga Senapati and Ron Moulder Mar. 1993 40 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F33615-89-C-5643)

(AD-A273175; WL-TR-93-4037) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The objective of this program was to demonstrate in the laboratory the feasibility of using ultrasonic energy to cure a structural adhesive used to bond two pieces of 2024-T3 aluminum. A process was developed that demonstrated that American Cyanamid FM-73 adhesive could be cured using ultrasonic energy at a power level of less than 25 watts/sq. inch of adhesive area. The bonds produced using ultrasonic energy were just as strong as the bonds produced using a thermal process. A styrene butadiene rubber was found to be an excellent material to couple the ultrasonic energy to the adhesive through the aluminum substrate. The required coupling pressure ranged from 10 to 15 psi. Ultrasonic energy is absorbed by the adhesive and is converted to heat. Fine thermocouples embedded in the adhesive showed that the temperature of the adhesive increased from room temperature (70 F) to 250 F in less than 10 minutes. The method currently used to cure the epoxy adhesive bonding a composite repair patch to an aircraft structure employs a heating blanket over the patch and the surrounding aircraft structure. This method is inefficient and requires the area surrounding a patch to be heated to the same temperature required to cure the adhesive. Since ultrasonic energy is absorbed directly by the adhesive, very little energy is wasted heating up the area surrounding the patch. Thus, an ultrasonic heating process is more efficient than the heating blanket method. The ultrasonic process has the potential to be used for repairing aging aircraft structures with bonded composite patches. DTIC

METAL-CATALYZED ALKYNYLATION OF BROMINATED POLYPHENYLENES: THERMOSET PRECURSORS OF HIGH DENSITY MONOLITHIC GLASSY CARBON Technical Report

Eric B. Stephens and James M. Tour 22 Nov. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-89-J-3062)

(AD-A273232; TR-21) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The functionalization of brominated polyphenylenes with several alkynes is described. The bromide groups on the polymer were replaced with terminal alkynes using a Pd/Cu catalyst system. Substitution of nearly all the original bromide locations was achieved. The functionalized polymers, freely soluble in THF, exhibited high char yields of up to 89% on thermolysis to 900 C under a nitrogen atmosphere. Several of the functionalized polymers, derived from brominated polyphenylenes with approximately equal amounts of meta- and para-linkages, flowed on heating. The polymer that was functionalized with phenylacetylene exhibited a well-defined melting point at approximately 200 C and flowed to produce a monolithic disk of glassy carbon. The amount of acetylenic crosslinking units in the polymers functionalized with phenylacetylene appears to be directly related to the char yields of the functionalized polymers. Predominantly meta-linked brominated polyphenylenes were also functionalized with a number of terminal alkynes and though high char yields of up to 86% were observed, these materials offered no improvements in flow properties. The structure/property relationships and material applications are discussed. DTIC

ELECTROCHEMICALLY MEDIATED POLYMERIZATION OF 2-PENTADECYLANILINE CONFINED TO A PLANAR LIQUID-LIQUID INTERFACE

Wolfgang M. Sigmund, Andrew D. Child, John R. Reynolds, and Randolph S. Duran 20 Oct. 1993 30 p

(Contract N00014-91-J-1655)

(AD-A273541; TR-11) Avail: CASI HC A03/MF A01

Spreading, isotherms, and polymerization of 2-pentadecylaniline at a planar aqueous electrolyte-organic interface were examined by monitoring the interfacial pressure employing the Wilhelmy-plate method. These results indicate the presence of monomer confined to the interface. Application of a voltage across the interface using stainless steel electrodes results in polymerization to form an electroactive polymer. The interfacial polymerization appears to be affected by metal ions formed by oxidation of the anode that have diffused into the aqueous electrolyte. This phenomenon is dependent on the nature of the electrode material as successful polymerization was not observed with other electrode materials. The polymer formed was soluble in polar organic liquids, was green in its reduced state, and blue in its oxidized state when oxidized and reduced chemically or electrochemically as a thin film. Cyclic voltammetry of the polymer indicates one reversible redox process suggesting that there are only two different oxidation states available, i.e., the equivalent to leucoemeraldine cannot be formed with poly(2-pentadecylaniline) in a thin film. However, the fully reduced yellow leucoemeraldine can be formed in chloroform solution by hydrazine reduction. DTIC

POLYTHIOPHENE DERIVATIVE WITH A SIDE CHAIN CHROMOPHORE AS PHOTOVOLTAIC AND PHOTOREFRACTIVE MATERIALS Technical Report
K. G. Chittibabu, L. Li, M. Kamath, J. Kumar, and S. K. Tripathy 17 Nov. 1993 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1148)
(AD-A273245; TR-94-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A new, solution processable, thiophene copolymer with a side chain nonlinear optical (NLO) chromophore namely Poly(3-octylthiophene co-N-(3-thenyl)-4-amino-2-nitro phenol) (POMDT) was chemically synthesized. The copolymer was further functionalized with a photocrosslinkable cinnamoyl group, and was doped with a photocrosslinkable NLO dye. The poled, photocrosslinked, dye doped copolymer exhibited relatively large second order NLO effects (d33 = 18.6 pm/V and 3.3 pm/V at 1.064 micrometers and 1.542 micrometers, respectively). The NLO properties of the photocrosslinked samples were stable at room temperature for 100 hours. The combination of reasonably good second order optical nonlinearity with established photoconducting behavior of the polythiophenes allows these type of polymers to be candidate materials in photovoltaic and photorefractive applications. ELECTROCHEMICAL AND ELECTRONIC PROPERTIES OF NEURAL AND OXIDIZED SOLUBLE ORTHOGONALLY-FUSED THIOPHENE OLIGOMERS Technical Report
J. Guay, A. Diaz, Ruilian Wu, and James M. Tour 22 Nov. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-3062)
(AD-A273283) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The chemical and electrooxidation of spiro-fused thiophene trimers, SIII, and spiro-fused thiophene heptamers, SVII, with terminal alpha-Si(CH3)3 and Beta-CH3 groups were studied in Ch2Cl2 at room temperature. The heptamer segments in SVII oxidize stepwise to produce the mono radical cation, the bis(radical cation), the radical cation/dication, and the bis(dication), respectively. The existence of these intermediate ions was confirmed by vis/near-IR and ESR analyzed. The presence of anodic peaks at different potentials for the removal of the first and second electron from SIII and SVII suggests that some interaction exists between the radical cation and the neutral oligomers. However, once both oligomers are there appears to be no significant electronic interactions between tbe orthogonally positioned heptamer cations except possibly some weak magnetic coupling. With SIII, the trimer segments oxidize at fairly anodic potentials, and the four sequential intermediates are not observed because the less stable cations probably dimerize to form a bis(spire structure) containing a thiophene hexamer cation. AQUEOUS ALKALINE CLEANERS: AN ALTERNATIVE TO ORGANIC SOLVENTS Final Report
Robert W. Bird and Bernard A. Donahue Sep. 1993 87 p
(AD-A273510; USACERL-TR-EP-93/05) Avail: CASI HC A05/MF A01

Cleaning metal parts is a common task at U.S. Army installations. Because solvents are generally used for this service, large quantities of hazardous waste are generated daily at posts around the world. The environmental impacts and escalating cost of waste disposal have prompted the Department of Defense (DOD) to initiate programs seeking safe and efficient methods to reduce solvent waste generation. In response, the U.S. Army Construction Engineering Research Laboratories (USACERL) initiated a study to investigate the use of alkaline cleaners as an alternative to organic solvents now being used. Alkaline cleaning is an age-old technology used extensively throughout the industry. Recently, the use of alkaline cleaners has increased due to the growing awareness of environmental and personnel safety concerns associated with chlorinated and petroleum-based solvents (i.e., 1,1,1- trichloroethane and Stoddard solvent). Properties associated with alkaline cleaners (i.e., nontoxic, nonvolatile, noncombustible, and biodegradable) make them an environmentally acceptable alternative for use in metal parts cleaning. The USACERL analysis found that aqueous alkaline cleaning systems can be an alternative for degreasing operations at U.S. Army installations. Due to the unique operating conditions at every base, each system should be thoroughly tested. Preliminary testing will ensure a proper system design that will benefit both the installation and the environment. DTIC

PLANAR POLY(p-PHENYLENE) DERIVATIVES: LADDER FORMATION FOR MAXIMIZATION OF EXTENDED CONJUGATION
James M. Tour and Jaydeep J. Lamba 22 Nov. 1993 8 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-3062)
(AD-A273220) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Described is the synthesis of ladder polymers with a poly(p-phenylene) (PPP) backbone. The main PPP backbone was synthesized via palladium-catalyzed coupling of an arylbis(boronic ester) with an aryldibromide. Imine bridges, formed by exposure of the polymer to trifluoroacetic acid or HCl, are used to force the consecutive units into planarity. The bridging units are sp2 hybridized, thus, allowing for greater pi-electron flow between the consecutive phenyl units by lowering the band gap between the hydroquinoidal and the quinoidal forms of the phenylene backbone. Upon planarization, bathochromic shifts of 210-240 nm occur for the n-dodecyl substituted polymer. The optical spectra of the planar systems are compared to that of the parent nonplanarized polymers, oligo(p-phenylenes), PPP, and other near-planar PPP derivatives. When the bridges are n-dodecyl substituted, the fully planar structures can be made into flexible free standing films. DTIC

THE 2-D POLYMERIZED LANGMUIR-BLODGETT FILMS STUDIED BY STM
T. S. Bailey, Wolfgang M. Sigmund, Randolph S. Duran, M. Hara, and H. Sasabe 20 Oct. 1993 17 p
(Contract N00014-91-J-1655)
(AD-A273542; TR-9) Avail: CASI HC A03/MF A01

The monomer 3-hexadecyl pyrrole was polymerized at the gas/liquid interface. Monomer and polymer were transferred from the interface to MoS2 for investigation by STM after annealing. Monolayers of monomer and polymer were highly ordered showing orientational and positional correlation of alkyl side chains. Polymer monolayers showed increased side chain packing density and side chain orientation more orthogonal to the surface. Polymer multilayers showed disorder, revealing connectivity and curvature of polymer chains. Conformations of polymer chains suggest growth in a parallel fashion at the gas/liquid interface. DTIC

INTELLIGENT CONTROL OF CHEMICAL VAPOR DEPOSITION PROCESSES Final Report, 1 Sep. 1990 - 31 Aug. 1993
Sunil Shah 1 Sep. 1993 87 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F49620-90-C-0066)
(AD-A273356; AFOSR-93-0847TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Significant progress has been made in improving process control on the Technion TB reactor by using a model-based approach to control design. This approach has led to improvements in two areas. First, it has made the control design process more efficient by reducing the time required by a trial and error approach. This will lead to a cost saving in manpower. Second, it has led to design of effective controllers whose design is not evident in a trial and error approach. This has led to improved regulation of actuation and deposition conditions. Both these improvements are expected to lead to a quicker deployment to new deposition strategies and eventually to the cost-effective production of diamond. Progress made under this contract has set the stage for further refinement and implementation of these control strategies in a production environment. Work in this area is under progress on a related contract with Norton Diamond film entitled 'Integration of Intelligent Process Control and Monitoring.' DTIC

INVESTIGATION OF THE ULTRAFILTRATION TECHNIQUE USING MILITARY GREASES Final Report
In-Sik Rhee Oct. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273633; BRDEC-TR/2544) Avail: CASI HC A03

Solid particle contamination in a grease intended for lubrication of instrument precision bearings can seriously degrade grease performance and bearing life. To produce clean grease, an ultrafiltration technique was recently introduced into the instrument bearing community. A major potential benefit of using this technique is that many instrument greases can be remanufactured from a variety of readily available lubricating greases. To assess this technique, an investigation was conducted to determine whether the physical and chemical properties of filtered greases are altered by the filtration process, and whether the filtered greases can improve instrument bearing life and their tribology properties. Results indicated that ultrafiltration can be performed on various types of greases with a substantial improvement in the resultant cleanliness level. However, some greases with rigid, discrete thickeners and solid additives are unlikely candidates for ultrafiltration due to their physical characteristic changes after filtering. DTIC

AN X RAY DIFFRACTION INVESTIGATION OF ALPHA-Al2O2 ADDITION TO YTTRIA STABILIZED ZIRCONIA (YSZ) THERMAL BARRIER COATINGS SUBJECT TO DESTABILIZING VANADIUM PENTOXIDE (V2O5) EXPOSURE M.S. Thesis
Dean M. Krestos Sep. 1993 79 p
(AD-A273403) Avail: CASI HC A05/MF A01

Since the mid 1970's the U.S. Navy has used yttria-stabilized zirconia (YSZ) as thermal barrier coatings for hot stage gas turbine components. Use of low cost, high contaminant, fuels has led to shortened component life from failure of YSZ coatings due to corrosive attack by vanadium and other combustion oxides. The object of this investigation was to determine the reactivity of adding alpha-Al2O3 to Current YSZ ceramics for creation of a ceramic composite which could improve mechanical properties and show improved durability to corrosive chemical attack. Ten powder samples of Zro2(8)Mol%YzO3, alpha-Al2O3, and V2Os5 of varying compositions were annealed at 900 C for 100 hours. X-ray diffraction analysis utilizing a standard 'search and match' method was used to determine the phases present in the reacted powder samples. Peak intensity comparisons between reacted and un-reacted samples allowed for a quantitative determination for the reactivity of a-A12O3 with the YSZ system exposed to V2O3. This investigation indicated that alpha-Al2O3 is non-reactive in all YSZ samples exposed to V2O5 at 900 C. DTIC

THE MEASUREMENT OF THE FILM THICKNESS AND THE ROUGHNESS DEFORMATION OF LUBRICATED ELASTOMERS Ph.D. Thesis
Marnix Visscher 1992 263 p
(ETN-94-95293) Avail: CASI HC A12/MF A03

A method for film thickness measurements, which has sufficient resolving power to detect the (eventual deformed) roughness texture, which is applicable to elastomeric seals or similar contacts, and in which a rough elastomer is in sliding contact with a smooth rigid body, was developed. Different methods were investigated on their suitability for the proposed measurements and the focus error detection method was chosen as the most appropriate. Further analysis of this method and some preliminary measurements showed its ability for film thickness measurements and the conditions which must be fulfilled. The method can also be used to measure the deformed roughness texture in a statically loaded glass to elastomer contact. Two series of measurements are presented, one with and the other without liquid in the contact area. It is shown that a liquid in the contact area can influence the contact situation significantly. The measurements on the dry contact yields the conclusion that real contact areas can be found at different length scales. Further investigation and development is needed to obtain the required accuracy and frequency range for the film thickness measurements. ESA

THE REACTION MECHANISM OF W-CVD IN Si Ph.D. Thesis
Paulus Adrianus Corn Groenen 1993 112 p Sponsored by Netherlands Foundation for Technical Sciences
(ETN-94-95329) Avail: CASI HC A06/MF A02

The Chemical Vapor Deposition of W (W-CVD) is investigated using WF6 as metal carrier. The study is performed in situ by a specially designed set up of a hot wall, continuous flow, full quartz reactor in combination with a mass spectrometer. The experimental apparatus is described. The reaction between WF6 and Si is studied. It results in a W layer of limited thickness. This reaction proceeds via a 'reaction layer' of about 80 atomic layers. This layer mainly consists of various fluorine containing species. The surface reaction between WF6 and SiH4 is investigated. This reaction is used to prevent Si consumption and to achieve thicker W layers. The study gives insights into the loss of selectivity. It is found that WF6 and SiH4 do react on a SiO2 surface. The result is a W containing species, that also acts as an independent reaction center and thus catalyzes the reaction. At approximately monolayer coverage, metallic W is formed. Based on the experimental observations, suggestions are made for the precursor state and the W containing species. ESA

THE EFFECTS OF ZINC BORATE ADDITION ON THE FLAMMABILITY CHARACTERISTICS OF POLYESTER, VINYL ESTER, AND EPOXY GLASS REINFORCED PLASTICS
Richard M. Morchat Oct. 1993 24 p
(AD-A273164; DREA-TM-93/214) Avail: CASI HC A03/MF A01

The effects of an inorganic fire-retardant additive, zinc borate, on flammability characteristics and smoke generation of glass reinforced polyester, vinyl ester, and epoxy resin were evaluated. Information is presented on the flame spread index (ASTM E162), limiting oxygen index (ASTM D2863), density of smoke generated (ASTM E662), and toxic gases of combustion (Boeing BSS 7239). Results indicated that the addition of 10 phr of zinc borate to the polymeric materials significantly decreased the flame spread index and increased the limiting oxygen index; however, the amount of smoke generated during pyrolytic and flaming combustion was high and unacceptable. Finally, the toxic gas evolution data indicated that the threshold limit values for some gases were exceeded. DTIC

SURFACE-INDUCED STATIC UNDULATIONS IN MULTILAYER FILMS OF LIQUID-CRYSTALLINE POLYMERS
R. E. Geer, R. Shashidar, A. F. Thibodeaux, and R. S. Duran 20 Oct. 1993 27 p
(Contract N00014-91-J-1655)
(AD-A273517; TR-10) Avail: CASI HC A03/MF A01

The first detailed study of surface-induced undulations in a liquid-crystalline polymer is presented. By examining the non-specular diffuse scattering from a 30-layer film of ferroelectric liquid-crystal polymer, it is shown that the layer fluctuations are induced by the roughness of the film/substrate interface. This is in contrast to the case of free-standing films wherein thermal fluctuations play the major role. DTIC

THE NANOSTRUCTURE OF MULTILAYERED FILMS: A NMR STUDY Ph.D. Thesis
Honore Alphonsus Mar deGronckel 1993 131 p Sponsored in part by EEC
(ETN-94-95347) Avail: CASI HC A07/MF A02

Experimental results on the possibilities of Nuclear Magnetic Resonance (NMR) for the structural characterization of multilayered films are presented. The origin of the magnetic field at the nucleus (the magnetic hyperfine field) and its dependence on the structural parameters are discussed. The set up and the phenomena governing signal intensity are described. The experimental results and the application of NMR to the study of crystallographic structure, strain and interface roughness, and topology in Co based multilayers are presented. NMR is not only sensitive to static properties through the positions, splittings, widths of the NMR spectra, but also to the dynamic properties of the electron spin system through the nuclear spin-lattice relaxation time. In principle, by combination of a static and dynamic NMR study, this offers the opportunity to study locally the electronic structure within the multilayer. ESA

MICROSTRUCTURE OF STYRENE METHYL METHACRYLATE COPOLYMERS GRAFTED ONTO POLYBUTADIENE SEEDS Ph.D. Thesis
Anna Maria Aerdts 1993 175 p Sponsored by General Electric Plastics
(ETN-94-95360) Avail: CASI HC A08/MF A02

An investigation aimed at a better understanding of the emulsion copolymerization of styrene and methyl methacrylate onto polybutadiene seed particles is described. Major relevant aspects of emulsion graft copolymerization are discussed. The determination of the intramolecular microstructure by proton Nuclear Magnetic Resonance (NMR) is described. The new peak assignment of the methoxy protons of styrene methyl methacrylate copolymers developed is confirmed by two dimensional NOESY (Nuclear Overhauser Effect Spectroscopy) NMR measurements. Due to the limited application of proton NMR to determine the intramolecular microstructure of styrene methyl methacrylate copolymers, the assignments of the carbon-13 NMR spectra are discussed. The free radical copolymerization models are critically examined and verified by measuring triad sequences by carbon-13 NMR. Experimental results and theoretical verification of the monomer partitioning experiments are discussed. The composition drift of grafted and free copolymer is studied in batch polymerizations. The copolymer composition, copolymer compositional distribution, the molecular weight, the degree of grafting, and grafting efficiency are obtained. The batch and semicontinuous graft polymerizations are investigated. The results comprise crucial information in terms of the degree of grafting, copolymer composition and compositional distribution and morphology, as a function of variation in the process conditions. LUBRICATION IN COLD ROLLING: NUMERICAL SIMULATION USING MULTIGRID TECHNIQUES Ph.D. Thesis
Pieter Martin Lugt 1992 194 p Sponsored by Aluminum Co. of America, PA, and Hoogovens, Ijmuiden, Netherlands
(ISBN-9-09-005313-1; ETN-94-95376) Copyright Avail: CASI HC A09/MF A03

A physical-mathematical model for predicting the quantity of lubricant between the rod and the strip is presented. The hydrodynamic approach is adopted. The running surfaces are assumed to be separated by a lubricant film and to deform elastically and/or plastically: the lubrication is called elasto-plasto-hydrodynamic. The elastic flattening of the rolls is described. Because of the complexity of the equations describing lubrication in cold rolling solution, several parameters can only be obtained if major simplifications are made. In order to avoid these simplifications a numerical approach is required. The equations are discretized on a grid covering the domain such that the solution of the resulting set of equations for all grid points approximates the solution of the continuous equation. The simulation model describing the smooth surface problem is presented. The numerical solution of the smooth surface problem is discussed. The equations are discretized and solved using these multigrid techniques. The results of the smooth surface problem are presented. Surface roughness effects are introduced. Two approaches are used: a simple friction multiplier, introduced to study the friction defect, and an empirical relation for the shear stresses on the surfaces. ESA

PARTICLE NUCLEATION AND GROWTH IN BUTADIENE EMULSION POLYMERIZATION Ph.D. Thesis
Edwin Maria F. J. Verdurmen 1993 201 p Sponsored by DSM, Geleen, Netherlands
(ETN-94-95300) Avail: CASI HC A10/MF A03

Results of a kinetic and mechanistic investigation of the butadiene emulsion polymerization are presented. The following were considered in order to elucidate on the main drawback of this polymerization, its low rate of polymerization: the value of the propagation rate coefficient; reasons why the rate g polymerization per particle is virtually independent of the persulfate concentration; and the additional effects that would be caused by using Tertiary Dodecyl Mercaptan (TDM) as a chain transfer agent. In order to solve these problems, well defined seeded emulsion polymerizations were performed on monodisperse seed latexes prepared by emulsifier free emulsion polymerization. The process of emulsifier free emulsion polymerization is described. ESA

PREPARATION AND PROPERTIES OF TRANSLUCENT GAMMA-ALUMINIUM OXYNITRIDE Ph.D. Thesis

Henricus Xavier Willems 1992 191 p Sponsored by Philips Lighting B.V., Netherlands
(Grant IOP-TK-88A022)
(ETN-94-95305) Avail: CASI HC A09/MF A02

The preparation and properties of gamma aluminum oxynitride (also called gamma Alon), a ceramic material being investigated as a replacement to aluminum oxide, which has the disadvantage of being corroded by sodium vapor, are addressed. The thermodynamical stability of the Alon phase and the use of Ellingham and activity diagrams to get information on this kind of system are considered. The width of the Alon homogeneity region in the Al2O3AlN system is determined for various temperatures and the relation between the lattice parameter and the Alon composition is obtained. Also the phase diagram of the Al2O3AlNMgO system is determined to get some insight in the possibility of obtaining solid solutions with a spinel type crystal structure in this (quaternary) system. The crystal structure of the Alon phase and neutron diffraction experiments that were performed in order to get some insight into the occupation of the different lattice sites are described. Powder processing and sintering details for the production of translucent Alons, and the effect of sintering additives on the sintering process and the resulting microstructures are considered. The electron transport properties, mechanical properties and optical properties of Alon are presented. ESA

EVALUATION OF MULTIAXIAL FRACTURE MODELS FOR TECHNICAL CERAMICS Ph.D. Thesis

Huibert Frank Scholten 1993 144 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant IOP-TK-88B040)
(ISBN-9-03-860192-1; ETN-94-95362) Avail: CASI HC A07

The modeling of the strength of technical ceramics under various loading conditions is considered. The brittle fracture process which largely determines the applicability of this group of materials is described. From a single defect, the statistical behavior of the strength of brittle materials is derived. A number of theoretical strength models from literature are discussed, which consist of the weakest link concept in combination with a fracture criterion. By means of a proper fracture criterion, it should be possible to predict failure under multiaxial loading conditions. Technical ceramics contain a large variety of microstructure, and another objective was to examine whether there is a link between best applicable fracture criterion and the type of microstructure. CRITICAL CURRENTS IN YBaCuO-CERAMICS

Yu. V. Obukhov 1991 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-617140; JINR-E-17-91-438) Avail: CASI HC A03 (US Sales Only)

The magnetization measurements on a ceramic YBaCuO sample were carried out. The M(H,T) dependence demonstrated some peculiarities which it was supposed to be connected with H(sub j1), H(sub j2), and H(sub c1) fields. By analyzing the magnetization in the field region between H(sub j1) and H(sub j2) within the frame of the critical state model one can find the dependence of the intergranular critical current density on field and temperature. TEMPLATE SYNTHESIS OF ELECTRONICALLY CONDUCTIVE POLYMERS

C. R. Martin, R. Parthasarathy, and V. Menon 1 Dec. 1993 17 p
(Contract N00014-82-K-0612)
(AD-A273673) Avail: CASI HC A03/MF A01

A method for synthesizing micro and nanoscopic fibers and tubules of electronically conductive polymers was developed. This method entails synthesis of the polymer within the pores of a microporous host membrane. Conductivities in the narrowest of these template-synthesized tubules and fibers can be significantly higher than in conventional forms (e.g. powders or thin films) of the analogous polymer. These previous conductivity data were based on a 2-point measurement of the resistance of the host membrane after synthesis of the conductive polymer fibers within this membrane. Results of conductivity measurements on thin films composed of the template-synthesized tubules and fibers are shown. A 4-point conductivity measurement was used on these thin films. These 4-point measurements corroborate the earlier 2-point conductivity data and, again, show that the template-synthesized materials are significantly more conductive. DTIC

A PRELIMINARY EVALUATION OF THE PHOSPHAZENE RESIN PPZ Final Report

Adam J. Jaglowski, Karin M. Gabriel, and Marc S. Pepi Oct. 1993 24 p
(AD-A273674; ARL-TR-223) Avail: CASI HC A03/MF A01

A phosphazene material, PPZTM, is reported by Idemitsu Petrochemical Company (Tokyo, Japan) to have excellent chemical and abrasion resistance properties for hardcoating applications. An evaluation of the chemical resistance of this coating is presented. PPZ coated on poly(ethylene terephthalate) (PET) films were challenged with simulants (2-chloroethyl ethyl sulfide (CEES), 2-chloroethyl methyl sulfide (CEMS), diisopropyl methyphosphonate (DIMP)) and a decontaminant (DS-2) via a droplet test method. Preliminary results showed that the PPZ coating was affected by DIMP, CEES, and CEMS as observed by optical and scanning electron microscopy (SEM). Upon visual examination, the DS-2 treated specimen did show an effect; however, the coating's behavior to this corrosion liquid is inconclusive. In addition, PPZ(TM) resin was coated on polycarbon (PC) using a modified ASTM D823-87 method and cured by ultraviolet light. Curing time was determined by Fourier transform infrared spectroscopy (FTIR) using an attenuated total reflectance (ATR) technique. The Taber abrasion resistance of the PPZ-coated PC specimens were slightly lower than reported values. DTIC

MORPHOLOGY OF HIGHLY TEXTURED POLYETHYLENE/POLYETHYLENE- PROPYLENE SEMICRYSTALLINE DIBLOCK COPOLYMERS

P. Kofinas and R. E. Cohen 3 Dec. 1993 41 p
(Contract N00014-91-J-1045)
(AD-A273683; TR-11) Avail: CASI HC A03/MF A01

A series of semicrystalline diblock copolymers of poly(ethylene)/poly(ethylenepropylene) (E/EP) were subjected to high levels of plane strain compression using a channel die. Deformations were imposed both below and above the melting point of the E block. The crystallographic and morphological textures were examined using wide-angle x ray diffraction pole figure analysis and two dimensional small-angle x ray scattering. The lattice unit cell orientation of the crystallized E chains with respect to the lamellar superstructure was determined, as well as the lamellar orientation relative to the specimen boundaries. When the diblocks are textured above the E block melting point at various compression ratios, the lamellae orient perpendicular to the plane of shear, while texturing below T, causes the lamellae to orient parallel to the plane of shear. The orientation of the crystallized E chains was perpendicular to the lamellar normal, irrespective of the texturing temperature. DTIC

THE IN SITU OBSERVATION OF EPITAXIAL DIAMOND THIN FILM NUCLEATION AND GROWTH USING EMISSION ELECTRON MICROSCOPY Semiannual Report, 1 Jan. - 31 Jun. 1993

Martin E. Kordesch Dec. 1993 40 p
(Contract N00014-91-J-1596)
(AD-A273698) Avail: CASI HC A03/MF A01

In situ observation of CVD diamond dissolution and etching using photoemission electron microscopy (PEEM) suggests that nucleation of diamond occurs directly on molybdenum, with a Mo-carbide bulk diffusion barrier that facilitates surface carbon transport for growth. Low energy electron microscopy of doped homoepitaxial C(100) is hindered by surface roughness, which is visible in PEEM. Charging observed with type IIa diamond is no longer present, but the high secondary electron yield is still problematic for direct imaging. TEM studies of CVD diamond grown directly on Mo TEM grids show a 10 nm thick amorphous C layer after growth, which is easily removable with an isopropanol rinse. LEED studies of Si(310) substrates for diamond growth show a (2X1) Si(310) reconstructed surface, with some faceting with fourfold symmetry. Nucleation is sparse and random on the Si(310) surfaces examined to date. DTIC

FEDERAL ALTERNATIVE FUEL PROGRAM LIGHT DUTY VEHICLE OPERATIONS
Jul. 1993 56 p
(DE93-040663; DOE/EE-0004) Avail: CASI HC A04/MF A01

This annual report to Congress details the second year of the Federal light duty vehicle operations as required by Section 400AA(b)(1)(B) of the Energy Policy and Conservation Act as amended by the Alternative Motor Fuels Act of 1988, Public Law 100-494. In 1992, the Federal alternative fuel vehicle fleet expanded significantly, from the 65 M85 (85 percent methanol and 15 percent unleaded gasoline) vehicles acquired in 1991 to an anticipated total of 3,267 light duty vehicles. Operating data are being collected from slightly over 20 percent, or 666, of these vehicles. The 601 additional vehicles that were added to the data collection program in 1992 include 75 compressed natural gas Dodge full-size (8-passenger) vans, 25 E85 (85 percent denatured ethanol and 15 percent unleaded gasoline) Chevrolet Lumina sedans, 250 M85 Dodge Spirit sedans (planned to begin operation in fiscal year 1993), and 251 compressed natural gas Chevrolet C-20 pickup trucks. The locations where the Federal light duty alternative fuel vehicles that are participating in the data collection program are operating are illustrated. The primary criteria for placement of vehicles will continue to include air quality attainment status and the availability of an alternative fuel infrastructure to support the vehicles. The second year of the Federal light duty vehicle operations, from October 1991 through September 1992, is detailed. DOE

PRELIMINARY STUDY CONCERNING DEVELOPMENT OF PETROLEUM-SUBSTITUTION ENERGY INTEGRATION TECHNOLOGY
Mar. 1993 172 p In JAPANESE
(DE94-714902; NEDO-P-9219) Avail: CASI HC A08/MF A02

With an objective to achieve compatibility among petroleum-substitution energy supply stability, energy efficiency, and energy demand, the energy utilization combining the conventional energy technologies is discussed.

First, the currently available individual technologies related to energy supply were sorted out focusing on substitution energies, and then the energy demand characteristics by fields were identified for the combined utilization. Using the results, evaluations were given on all of the combinations of individual technologies using as parameters the demand characteristics, environment preserving effect, novelty, and supply stability. Parallel use with conventional technologies was represented by hybrid use of photovoltaic power generation with solar heat collectors, paralleling heat supply using wind power with biomass utilization, and photovoltaic power generation with fuel cells. Selected series use with conventional technologies include a Stirling engine using heat collected by solar heat collectors, coal liquefaction and gasification using underground heat, a heat pump driven by solar energy generated power, regional heat supply using underground heat, and biomass fuel cells. Followability to regional demand characteristics and demand variation is important. DOE

THE IGNITION TEMPERATURE OF SOLID EXPLOSIVES EXPOSED TO A FIRE
J. R. Creighton Sep. 1993 8 p Presented at the PSAM Conference, San Diego, CA, 20-24 Mar. 1993
(Contract W-7405-eng-48)
(DE94-001047; UCRL-JC-114201; CONF-9303221-2) Avail: CASI HC A02/MF A01

When a system containing solid explosives is engulfed in a fire it receives a heat flux that causes the temperature of the system to rise monotonically. The temperature rise can often be approximated by a linear rise for extended periods of time. When some portion of the explosive, usually near the surface, reaches its ignition temperature, it will begin to burn. If the explosive is unconfined, or can breach its confinement at low pressure, it will burn, not explode. Typically the burn front will propagate through a slab or shell at speeds on the order of a centimeter a minute. If the explosive is confined, the gas resulting from its burning will generate pressures high enough to rupture the confinement, but the peak pressure will generally be only a fraction of the pressure from a true detonation. When a system is not engulfed in the fire, but is close enough to be heated slowly by the fire, the behavior will be different. If the explosive is heated slowly it will have a nearly uniform temperature and ignition will occur inside the explosive. This almost always causes an explosion, even when the explosive as a whole is unconfined. The reason for this behavior is not well understood but slow heating of an explosive generally results in a more violent explosion than fast heating. These two situations are recognized by fast and slow cookoff tests used with munitions. Many munitions pass the fast cookoff test with heating rates around 2 K/min. Slow cookoff tests with heating rates around 4 K/hr generally result in an explosion. (The equations in this paper assume absolute temperatures in Kelvins, equal to Celsius + 273.16.) Mathematical models predicting the time to explosion are usually based on the assumption that the explosive has a uniform initial temperature and that the outer surface is suddenly raised to some temperature and held there. The earliest such models where those of Semenov and Frank-Kamenetskii. DOE

ENERGY TRANSFER IN SOLID EXPLOSIVES
C. M. Tarver, L. E. Fried, A. J. Ruggiero, and D. F. Calef Jul. 1993 9 p Presented at the 10th Detonation Symposium, Boston, MA, 12-16 Jul. 1993
(Contract W-7405-eng-48)
(DE94-001523; UCRL-JC-111343; CONF-930713-32) Avail: CASI HC A02/MF A01

The nonequilibrium Zeldovich-von Neumann-Doring theory of detonation in solid explosives is extended to include recent nanosecond and picosecond experimental and theoretical results on each of the four main regions of the reaction zone. The first region is the three-dimensional, Mach stem dominated leading shock front which excites the phonon modes of the explosive molecules in less than a picosecond. The second region is the multiphonon up-pumping process in which the excited phonons anharmonically couple to the low frequency (doorway) vibrational modes which in turn equilibrate with the higher frequency modes by internal vibrational redistribution. This process may require on the order of tens of picoseconds. The third region is the chemical reconstitution region in which the vibrationally equilibrated transition state decomposes in a series of chain reaction steps into vibrationally excited diatomic and triatomic molecules in approximately one nanosecond. The fourth region is dominated by vibrational deexcitation and solid species formation as chemical and thermal equilibrium is approached. This is the region measured by current nanosecond resolution techniques and can last from nanoseconds to microseconds depending on the oxygen balance of the solid explosive. DOE

MULTIPLE SHOCK INITIATION OF LX-17
C. M. Tarver, T. M. Cook, P. A. Urtiew, and W. C. Tao Jul. 1993 10 p Presented at the 10th Detonation Symposium, Boston, MA, 12-16 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print
(Contract W-7405-eng-48)
(DE94-001524; UCRL-JC-111342; CONF-930713-30) Avail: Issuing Activity (Department of Energy (DOE))

The response of the insensitive TATB-based high explosive LX-17 to multiple shock impacts is studied experimentally in a four inch gas gun using embedded manganin gauges and numerically using the ignition and growth reactive flow model of shock initiation and detonation. Pressure histories are reported for LX-17 cylinders which are subjected to sustained shock pulses followed by secondary compressions from shocks reflected from metal discs attached to the backs of the explosive targets. These measured and calculated pressure histories show that the threshold for hot spot growth in LX-17 is 7 GPa, that LX-17 can be dead pressed at slightly lower pressures, and that the reaction rates behind reflected shocks increase greatly as the impedance of the metal increases. A study of the response of LX-17 to the collision of two reacting, diverging shocks forming a Mach stem wave inside the LX-17 charge demonstrated that this interaction can result in a high pressure region of sufficient size and strength to cause detonation under certain conditions. DISCRETE SENSITIVITY DERIVATIVES OF THE NAVIER-STOKES EQUATIONS WITH A PARALLEL KRYLOV SOLVER
Kumud Ajmani and Arthur C. Taylor, III (Old Dominion Univ., Norfolk, VA.) Jan. 1994 13 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106481; ICOMP-94-2; E-8411; NAS 1.15:106481; AIAA Paper 94-0091) Avail: CASI HC A03/MF A01

This paper solves an 'incremental' form of the sensitivity equations derived by differentiating the discretized thin-layer Navier Stokes equations with respect to certain design variables of interest. The equations are solved with a parallel, preconditioned Generalized Minimal RESidual (GMRES) solver on a distributed-memory architecture. The 'serial' sensitivity analysis code is parallelized by using the Single Program Multiple Data (SPMD) programming model, domain decomposition techniques, and message-passing tools. Sensitivity derivatives are computed for low and high Reynolds number flows over a NACA 1406 airfoil on a 32-processor Intel Hypercube, and found to be identical to those computed on a single-processor Cray Y-MP. It is estimated that the parallel sensitivity analysis code has to be run on 40-50 processors of the Intel Hypercube in order to match the single-processor processing time of a Cray Y-MP. SOLID ROCKET COMBUSTION SIMULATOR TECHNOLOGY USING THE HYBRID ROCKET FOR SIMULATION Final Report, 16 Jul. 1991 - 23 Jul. 1993
Kumar Ramohalli 22 Feb. 1994 56 p
(Grant NAG8-883)
(NASA-CR-195142; NAS 1.26:195142) Avail: CASI HC A04/MF A01

The hybrid rocket is reexamined in light of several important unanswered questions regarding its performance. The well-known heat transfer limited burning rate equation is quoted, and its limitations are pointed out. Several inconsistencies in the burning rate determination through fuel depolymerization are explicitly discussed. The resolution appears to be through the postulate of (surface) oxidative degradation of the fuel.

Experiments are initiated to study the fuel degradation in mixtures of nitrogen/oxygen in the 99.9 percent/0.1 percent to 98 percent/2 percent range. The overall hybrid combustion behavior is studied in a 2 in-diameter rocket motor, where a PMMA tube is used as the fuel. The results include detailed, real-time infrared video images of the combustion zone. Space- and time-averaged images give a broad indication of the temperature reached in the gases. A brief outline is shown of future work, which will specifically concentrate on the exploration of the role of the oxidizer transport to the fuel surface, and the role of the unburned fuel that is reported to escape below the classical time-averaged boundary layer flame. Mankind's exploration of space will eventually lead to the establishment of a permanent human presence on the Moon. Essential to the economic viability of such an undertaking will be prudent utilization of indigenous lunar resources. The design of a lunar propellant processing system is presented. The system elements include facilities for ore processing, ice transportation, water splitting, propellant storage, personnel and materials transportation, human habitation, power generation, and communications. The design scenario postulates that ice is present in the lunar polar regions, and that an initial lunar outpost was established. Mining, ore processing, and water transportation operations are located in the polar regions. Water processing and propellant storage facilities are positioned near the equator. A general description of design operations is outlined below. Regolith containing the ice is mined from permanently-shaded polar craters. Water is separated from the ore using a microwave processing technique, and refrozen into projectiles for launch to the equatorial site via railgun. A mass-catching device retrieves the ice. This ice is processed using fractional distillation to remove impurities, and the purified liquid water is fed to an electrolytic cell that splits the water into vaporous hydrogen and oxygen. The hydrogen and oxygen are condensed and stored separately in a tank farm. Electric power for all operations is supplied by SP-100 nuclear reactors. Transportation of materials and personnel is accomplished primarily using chemical rockets. Modular living habitats are used which provide flexibility for the placement and number of personnel. A communications system consisting of lunar surface terminals, a lunar relay satellite, and terrestrial surface stations provides capabilities for continuous Moon-Moon and Moon-Earth transmissions of voice, picture, and data. Experimental and analytical investigations focusing on aluminum/hydrocarbon gel droplet secondary atomization and its effects on gel-fueled rocket engine performance are being conducted. A single laser sheet sizing/velocimetry diagnostic technique, which should eliminate sizing bias in the data collection process, has been designed and constructed to overcome limitations of the two-color forward-scatter technique used in previous work. Calibration of this system is in progress and the data acquisition/validation code is being written. Narrow-band measurements of radiant emission, discussed in previous reports, will be used to determine if aluminum ignition has occurred in a gel droplet. A one-dimensional model of a gel-fueled rocket combustion chamber, described in earlier reports, has been exercised in conjunction with a two-dimensional, two-phase nozzle code to predict the performance of an aluminum/hydrocarbon fueled engine. Estimated secondary atomization effects on propellant burnout distance, condensed particle radiation losses to the chamber walls, and nozzle two phase flow losses are also investigated. Calculations indicate that only modest secondary atomization is required to significantly reduce propellant burnout distances, aluminum oxide residual size, and radiation heat losses. Radiation losses equal to approximately 2-13 percent of the energy released during combustion were estimated, depending on secondary atomization intensity. A two-dimensional, two-phase nozzle code was employed to estimate radiation and nozzle two phase flow effects on overall engine performance. Radiation losses yielded a one percent decrease in engine Isp. Results also indicate that secondary atomization may have less effect on two-phase losses than it does on propellant burnout distance and no effect if oxide particle coagulation and shear induced droplet breakup govern oxide particle size. Engine Isp was found to decrease from 337.4 to 293.7 seconds as gel aluminum mass loading was varied from 0-70 wt percent. Engine Isp efficiencies, accounting for radiation and two phase flow effects, on the order of 0.946 were calculated for a 60 wt percent gel, assuming a fragmentation ratio of five. Author (revised)

ISOTHIAZOLONE VOLATILITY STUDY OF A WATER BOTTOM FROM FUEL TREATED WITH KATHON (TM) FP1.5 BIOCIDE
R. D. Haggett and Richard M. Morchat Nov. 1993 23 p
(AD-A273165; DREA-TM-93/216) Avail: CASI HC A03/MF A01

An analytical method based on the gas chromatographic / mass spectrometry separation and detection of the two isothiazolones (5-chloro-2-methyl- 4-isothiazolin- 3-one and 2-methyl- 4-isothiazolin- 3-one), the active ingredients in one commercially available biocide used to treat fuel systems contaminated with microbiological growth, is described. A modification of this method, to allow static headspace detection of these isothiazolones, is also described. Results of experiments using the modified technique demonstrated that these two compounds do not volatilize from a sea water solution at temperatures up to 70 C. This suggests that un-depleted isothiazolone in the water bottom of fuel tanks treated with Kathon FP1.5 biocide would not volatilize into the habitable air space above the bilge to generate toxic components that could then be inhaled by the personnel working in the immediate vicinity. RESPONSE OF AN ANCHORED ANNULAR CYLINDRICAL LIQUID LAYER TO VARIOUS AXIAL EXCITATIONS IN ZERO-GRAVITY
Helmut F. Bauer 1992 22 p
(LRT-WE-9-FB-3-1992; ETN-94-95088) Avail: CASI HC A03/MF A01

An annular liquid layer is subjected in a zero gravity environment to different harmonic axial excitations. The liquid is treated as frictionless and is held together by free surface tension, which acts as the restoring force. The layer is placed between two parallel and concentric discs, at which rim it is, due to surface tension, anchored. The response of the system was determined for the free surface elevation and the velocity distribution. It was found, that the first resonance response is sharply tuned and could easily be missed in a sweeping experiment. The resonance peaks are at larger frequencies in comparison with those of an annular layer with freely slipping edges. ESA

(Contract NAS8-38785)
(NASA-CR-194804; NAS 1.26:194804) Avail: CASI HC A03/MF A01

Contract NAS8-38785, Microgravity Experimental and Theoretical Research, is a project involving a large number of individual research programs related to: determination of the structure of human serum albumin and other biomedically important proteins; analysis of thermodynamic properties of various proteins and models of protein nucleation; development of experimental techniques for the growth of protein crystals in space; study of the physics of electrical double layers in the mechanics of liquid interfaces; computational analysis of vapor crystal growth processes in microgravity; analysis of the influence of magnetic fields in damping residual flows in directional solidification processes; crystal growth and characterization of II-VI semiconductor alloys; and production of thin films for nonlinear optics. It is not intended that the programs will be necessarily limited to this set at any one time. The visiting scientists accomplishing these programs shall serve on-site at MSFC to take advantage of existing laboratory facilities and the daily opportunities for technical communications with various senior scientists. STUDIES OF TWO PHASE FLOW Final Report, Sep. 1991 - Nov. 1993
Larry C. Witte Feb. 1994 4 p
(Grant NAG9-546)
(NASA-CR-195099; NAS 1.26:195099; UH-BUDGET-1-5-54282) Avail: CASI HC A01/MF A01

The development of instrumentation for the support of research in two-phase flow in simulated microgravity conditions was performed. The funds were expended in the development of a technique for characterizing the motion and size distribution of small liquid droplets dispersed in a flowing gas. Phenomena like this occur in both microgravity and normal earth gravity situations inside of conduits that are carrying liquid-vapor mixtures at high flow rates. Some effort to develop a conductance probe for the measurement of liquid film thickness was also expended. Author (revised)

THE INFLUENCE OF FLOW TYPE, PARTICLE TYPE AND GRAVITY ON ORTHOKINETIC COAGULATION Ph.D. Thesis
Lambertus Leonardus Krutzer 1993 111 p
(ETN-94-95333) Avail: CASI HC A06/MF A02

A study to obtain insight into some parameters determining the coagulation process is reported: the influence of the type of flow (laminar or turbulent), the influence of the kind of particles (size, density, and initial size distribution) and the influence of gravity are investigated. Theories describing the different forms of coagulation and the equations describing the interaction forces between the particles are summarized. Some methods to measure aggregation are described. The influence of the flow type on the coagulation rate of a polystyrene latex was studied. Experiments were performed in a Couette device, in laminar pipe flow and in an isotropic turbulent flow field. By studying the coagulation behavior of polystyrene, glass, quartz particles and silicaspheres, some insight into the influence of the initial size distribution, the influence of a density difference between the disperse and continuous phases, and the influence of the particle shape on the coagulation rate was obtained. Because coagulation experiments of particles having a density difference with the continuous phase cannot be performed at low shear rates, some microgravity coagulation experiments were performed. In these experiments quartz particles were coagulated at low stirring speeds. ESA

DEVELOPMENT AND EXPERIMENTAL VALIDATION OF COMPUTATIONAL METHODS TO SIMULATE ABNORMAL THERMAL AND STRUCTURAL ENVIRONMENTS

J. L. Moya, R. D. Skocypec, and R. K. Thomas 1993 13 p Presented at the Surety Technology Symposium, Chelyacinsk, Russia, 28 Sep. - 2 Oct. 1993
(Contract DE-AC04-76DP-00789)
(DE94-000554; SAND-93-2215C; CONF-9309215-3) Avail: CASI HC A03/MF A01

Over the past 40 years, Sandia National Laboratories (SNL) has been actively engaged in research to improve the ability to accurately predict the response of engineered systems to abnormal thermal and structural environments. These engineered systems contain very hazardous materials. Assessing the degree of safety/risk afforded the public and environment by these engineered systems, therefore, is of upmost importance. The ability to accurately predict the response of these systems to accidents (to abnormal environments) is required to assess the degree of safety. Before the effect of the abnormal environment on these systems can be determined, it is necessary to ascertain the nature of the environment. Ascertaining the nature of the environment, in turn, requires the ability to physically characterize and numerically simulate the abnormal environment. Historically, SNL has demonstrated the level of safety provided by these engineered systems by either of two approaches: a purely regulatory approach, or by a probabilistic risk assessment (PRA). This paper will address the latter of the two approaches. DOE

FLUE GAS CLEANING BY PULSE CORONA STREAMER

Yan Keping (Beijing Inst. of Tech., China.) and E. M. vanVeldhuizen Mar. 1993 81 p Sponsored by Netherlands Organization for Scientific Research
(EUT-93-E-272; ISBN-9-06-144272-9; ETN-94-94779) Avail: CASI HC A05/MF A01

Currents of up to 600 A are obtained on a corona wire of 1 m length by applying DC and pulse voltage. The energy input is upto 6 J/pulse. The current duration is between 100 and 600 ns, and depends strongly on the DC voltage, the stray inductance and resistance of the circuit. Breakdown can be avoided by choosing the appropriate values for the components in the pulse circuit. Average electron energies resolved in space and in time are obtained by means of optical spectroscopy for corona discharge streamers in a wire cylinder reactor in air and in flue gas. The electron energy for primary streamers in air is found to be in the order of 10 eV and increases slightly with the pulse voltage and is almost constant during the streamer propagation. The electron energy for the secondary streamer is about a factor two lower near the anode where its optical emission is strong. In the gap and near the cathode, its emission is much less and the electron energy is another three times lower. The secondary streamer is limited in length, because it must satisfy the stability field requirement. The larger attachment coefficient of flue gas in the low field region explains that in flue gas the secondary streamer is shorter than in air. The ratio of the electrical energy input into primary and secondary streamers is controlled by the length of the electrical pulse. Measurements of NO removal from flue gas indicate that a pulse duration equal to the time required by the primary streamer to cross the gap gives the highest cleaning efficiency. ESA

EXTINGUISHMENT OF ENCLOSED GAS FIRES WITH WATER SPRAYS

R. Wighus (Norges Tekniske Hoegskole, Trondheim.) 23 Feb. 1993 14 p See also PB92-151273 Sponsored by Royal Norwegian Council for Scientific and Industrial Research and Norsk Hydro Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-201663; STF25-A92051) Avail: Issuing Activity (National Technical Information Service (NTIS))

Water sprays are widely used for fire fighting in industrial areas, and they are used for fire protection in the process industry and at offshore oil- and gas-production platforms. No real quantification of the effect of water sprays as a fire fighting medium exists. The water delivery is specified through standards and regulations which are based on industrial experience. In process areas, water spray is often used in deluge systems, intended to control the fire until the leakage of fuel has been shut down. For this purpose, there is a need for quantification of the ability a certain spray system has to remove heat from the fire and to reduce the fire load to the construction and process equipment. SINTEF NBL has studied extinguishment and control of enclosed hydrocarbon fires by means of water sprays. A scale model of a module of an offshore platform is used in studies of enclosed liquid hydrocarbon fire development. The model is instrumented to measure heat transfer, fire development, and production of soot and gases from combustion. NTIS

CALCULATION OF FLAME SPREAD ON LINING MATERIALS BY THE FIELD MODEL KAMELEON. PROJECT 5 OF THE EUREFIC FIRE RESEARCH PROGRAMME

K. Opstad (Norges Tekniske Hoegskole, Trondheim.) 22 Jan. 1993 37 p See also PB88-201330, PB91-188409, PB92-109875, PB92-142785 and PB92-151281 Sponsored by NORDTEST and Nordisk Industrifond Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-201614; STF25-A92016) Avail: Issuing Activity (National Technical Information Service (NTIS))

An advanced calculation tool for flame spread calculation is under development. The system is based on the cone calorimeter test results. The heat release properties as a function of the irradiation level and thermal properties for combustible materials are derived from the cone calorimeter results. These data are implemented into a field model, which already has the capabilities to handle reacting fluids (combustion). Soot radiation and blocking as well as soot production are considered. Several calculated scenarios in enclosed environment are given. The results are promising, especially in the way of predicting the main factors of fire development, heat release rate, area which is burning, unburnt fuel, ventilation rate and the internal flow field. The only input is the geometry, ventilation, lining product and ignition source. NTIS

SYSTEMS ENGINEERING: A FORMAL APPROACH. PART 1: SYSTEM CONCEPTS

K. M. vanHee 30 Mar. 1993 95 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-225308; CSN-93/09) Copyright Avail: CASI HC A05

Engineering is the scientific discipline focused on the creation of new artifacts that are supposed to be of some use to our society. Different types of artifacts require different engineering approaches. However, in all these disciplines the development of a new artifact is divided into stages. Three stages can always be recognized: Analysis, Design, and Realization. The book considers only the first two stages of the development process. It focuses on a specific type of artifacts, called discrete dynamic systems. These systems consist of active components of actors that consume and produce passive components or tokens. Three subtypes are studied in more detail: business systems (like a factory or restaurant), information systems (whether automated or not), and automated systems (systems that are controlled by an automated information system). The first subtype is studied by industrial engineers, the last by software engineers and electrical engineers, whereas the second is a battlefield for all three disciplines. The union of these disciplines is called systems engineering. NTIS

FIELD MODELS: THEIR PRESENT AND FUTURE APPLICATION IN FIRE SAFETY ENGINEERING

K. S. Pedersen and B. F. Magnussen (Norges Tekniske Hoegskole, Trondheim.) 29 Dec. 1992 15 p See also PB93-201630 and PB93-162659 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-201622; STF25-A92041) Avail: Issuing Activity (National Technical Information Service (NTIS))

Different field models for calculating heat load, fire development, and smoke concentrations have been developed for use in fire safety engineering work. The field model versions of KAMELEON are based on a finite difference solution of the basic equations from fluid dynamics together with different mathematical models. The most important of these models are the kappa-epsilon model of turbulence, the eddy dissipation concept of combustion (EDC), the soot model by Magnussen, and the discrete transfer model for radiation by Shah and Lockwood. All the resulting equations are solved three dimensionally and in transient. A version under development is a calculation tool for flame spread on surface linings. The system uses input data from the cone calorimeter. The paper will mainly deal with the description of the numerical code and especially a version called KAMELEON FIRE E-3D, handling enclosed pool fires. NTIS

Rotating unbalanced-mass (RUM) devices are a new way to scan space-based, balloon-borne, and ground-based gimbaled payloads, like x-ray and gamma-ray telescopes. They can also be used to scan free-flying spacecraft. Circular scans, linear scans, and raster scans can be generated. A pair of RUM devices generates the basic scan motion and an auxiliary control system using torque motors, control moment gyros, or reaction wheels keeps the scan centered on the target and produces some complementary motion for raster scanning. Previous analyses and simulation results show that this approach offers significant power savings compared to scanning only with the auxiliary control system, especially with large payloads and high scan frequencies. However, these claims have never been proven until now. This paper describes a laboratory experiment which tests the concept of scanning a gimbaled payload with RUM devices. A description of the experiment is given and test results that prove the concept are presented. The test results are compared with those from a computer simulation model of the experiment and the differences are discussed. Author

RAIL CORRUGATIONS

Klaus Knothe, ed. 1992 126 p Papers presented at Symposium on Corrugation Problems, Berlin, Germany, 17 Apr. 1991
(ILR-BER-59; ISBN-3-7983-1505-1; ETN-93-94176) Avail: CASI HC A07/MF A02

The following topics were discussed: a rail corrugation theory, the possible initiator of corrugation in a rail joint, the limits of validity of a linear model for corrugation, lateral high frequency oscillations and stability of a wheel rolling on a flexible track, the wear characteristics of dry rolling/sliding systems, surface analysis of corrugated rail treads, the observation of stick slip oscillations in tightly conformal wheel/rail contacts, an contact analysis of rough rail surfaces. For individual titles, see N94-23582 through N94-23589.

A RAIL CORRUGATION THEORY WHICH ALLOWS FOR CONTACT PATCH SIZE

C. O. Frederick and J. C. Sinclair *In* Tech. Univ. Berlin, Rail Congurations 1992 p 1-27 (For primary document see N94-23581 06-31)
Avail: CASI HC A03/MF A02

A small creepage rail corrugation theory is presented. The formulation is based on infinitesimally small fluctuation approach, which was extended to allow a finite length contact patch between the wheel and the rail. The theory considers curvature interactions between the wheel, the rail's transverse profile and the potential corrugation wave. The corrugation behavior is influenced by the interaction between track and wheelset dynamics and other factors which control the wheel/rail contact conditions. Subtle changes in these conditions alter the corrugation behavior. The effect of wheel radius and transverse rail head shape on corrugation behavior, consistent with observations, are predicted. The effect of contact patch filtering suppressing short wavelength corrugations becomes significant for low vehicle speeds. An improved simulation of corrugated behavior may be obtained. ESA

A RAIL JOINT: THE POSSIBLE INITIATOR OF CORRUGATION?

G. Hoelzl *In* Tech. Univ. Berlin, Rail Corrugations 1992 p 29-40 (For primary document see N94-23581 06-31)
Avail: CASI HC A03/MF A02

The corrugation found at a rail joint which seems to be the initiator of the formation of corrugation is investigated. The possibility that the development of corrugations depends on the magnitude of the traffic is discussed. Several corrugation profiles and roughness spectra were measured. The results indicate that the corrugation can be caused by the start of the locomotives motion at the rail road crossing. Such corrugations were also found in stations at places where locomotives usually start to move. ESA

A LINEAR MODEL FOR CORRUGATION AND ITS LIMIT OF VALIDITY

Klaus Hempelmann, Arnold Gross-Thebing, and Klaus Knothe *In its* Rail Corrugations 1992 p 41-57 (For primary document see N94-23581 06-31)
Avail: CASI HC A03/MF A02

A model to predict corrugation patterns and wavelength distributions developing out of initial disturbances is presented. The purpose is to show how a modeling of the contact mechanics, especially the so called curvature excitation, will influence the results. The influence of structural dynamics of the wheelset and here especially of the crosscoupling of vertical and lateral dynamics is investigated. The model indicates that a feedback mechanism between structural dynamics and wear is responsible for the initiation of corrugations on the rail tread. ESA

LATERAL HIGH FREQUENCY OSCILLATIONS AND STABILITY OF A WHEEL ROLLING ON A FLEXIBLE TRACK

E. Brommundt *In* Tech. Univ. Berlin, Rail Corrugations 1992 p 59-74 (For primary document see N94-23581 06-31)
Avail: CASI HC A03/MF A02

A model for studying the stability and the lateral deformations of the wheel under high frequency oscillations is proposed. The model is based on linearized equations for a single laterally flexible wheel with a cylindrical surface, running on a viscoelastically founded Euler-Bernoulli beam. The point contact and Kalker's linearized theory for oscillatory contact behavior are assumed to hold for the rolling motion. The equations of motion and a solution procedure are presented. ESA

N94-23586# Technische Univ., Berlin (Germany). Inst. fuer Fahrzeugtechnik.

WEAR CHARACTERISTICS OF TECHNICAL DRY ROLLING/SLIDING SYSTEMS WITH RELATIONS TO CORRUGATION PROBLEMS

H. Lehna *In its* Rail Corrugations 1992 p 75-84 (For primary document see N94-23581 06-31)
Avail: CASI HC A02/MF A02

Corrugation problems induced by wear in rail/wheel system of railways are investigated. The purposes of the study are: optimizing the wear behavior, attaining knowledge about the considered wear process, finding out wear quantities and their relevant value range, and determining wear laws to make wear calculable. Experimental investigations were performed and wear characteristics were examined. A rolling/sliding test rig with cylindrical rollers measuring 50 mm in diameter and 6 mm in contact patch width were used. The rollers operating at different circumferential velocities were pressed against each other. The normal load was applied hydraulically. Carbon steel, Ck 60, was used for the driving and the driven rollers. The entire investigation program comprised 41 combinations of control values of the operational quantities normal force, creepage, and driving rotational speed. ESA

SURFACE ANALYSIS OF CORRUGATED RAIL TREADS
H. G. Feller and K. Walf *In its* Rail Corrugations 1992 p 85-94
Sponsored by DFG (For primary document see N94-23581 06-31)
Avail: CASI HC A02/MF A02

Corrugated rail treads were examined by surface analysis. The aim was to obtain information on the friction and wear behavior of the system wheel/rail and on the formation of corrugation. Surface geometry, surface morphology, structure, hardness values, and chemical composition analyses were performed. The results lead to the conclusion that the vibration of the wheel/tread system leads to different amounts of loads at different areas at the surface. As a consequence, areas with higher loads, higher deformation, higher hardening and higher wear resistance, the 'hills' were found. Neighboring areas of lower deformation, the 'valleys' were observed. The valleys are deepened by wear, which is followed by corrosion attack. ESA

SURFACE OBSERVATIONS OF STICK-SLIP OSCILLATIONS IN TIGHTLY CONFORMAL WHEEL/RAIL CONTACTS
J. Kalousek *In* Tech. Univ. Berlin, Rail Corrugations 1992 p 95-111
(For primary document see N94-23581 06-31)
Avail: CASI HC A03/MF A02

The reasons for the growth of corrugations on rails and wheels in the Vancouver (Canada) mass transit system are described. The measures taken to eliminate them are outlined. In the Vancouver transit system, by design, the longitudinal and lateral creepages in the wheel/rail interface were absent. The fastener subassembly contains a 25 mm thick layer of natural rubber to absorb vibrations and provide the desired resiliency. The track gauge is maintained to an accuracy of +/- 1 mm. According to the corrugation theories, the lack of longitudinal and lateral creepage in the rail wheel interface was expected to keep the system free from wheel rail vibrations, excessive noise, and corrugations. Yet, six months after opening, 85% of the track was corrugated and the noise levels were rather high. The corrugations on the rails and the wheels are eliminated by means of controlling the friction characteristic and the conformity of rail wheel profiles. ESA

CONTACT ANALYSIS OF ROUGH RAIL SURFACES
G. Wang and K. Knothe *In its* Rail Corrugations 1992 p 113-120
(For primary document see N94-23581 06-31)
Avail: CASI HC A02/MF A02

A stress analysis in the contact region and in the thin layer below the rail surface was carried out. An experimentally measured profilogram of a well used rail surface was applied. The stress analysis is performed by a two dimensional contact mechanical calculation where Coulomb's friction is taken into account. Stress distributions in the contact area and the lines of equal von Mises yield Stress in the elastic body are given. A rough surface of rail track was simulated by overlapping a selected section from a profilogram into a plane. The calculation showed that the remaining profile roughness may be responsible for high von Mises stress in a thin layer of about 100 to 40 micrometers. ESA

ZONE FIRE MODELING WITH NATURAL BUILDING FLOWS AND A ZERO ORDER SHAFT MODEL
J. H. Klote and G. P. Forney Sep. 1993 43 p
(PB94-112166; NISTIR-5251) Avail: CASI HC A03/MF A01

The paper addresses applications of zone fire models to simulate smoke flow in multistory buildings. Natural flows in buildings are discussed. A zero order model for shaft smoke flow was developed which treated the shaft as one perfectly mixed zone. A two zone fire model was modified to simulate natural flows and the zero order shaft smoke flow. The extent to which the one zone model and the two zone model are appropriate to simulate smoke flow in shafts is discussed. NTIS

LASER SOLDERING OF Sn PLATED BRASS INTEGRATOR ASSEMBLY HOUSINGS
D. M. Keicher, G. A. Poulter, and N. R. Sorensen Sep. 1993 9 p
Presented at the 1993 International Congress on Application of Lasers and Electro-Optics, Orlando, FL, 24-28 Oct. 1993
(Contract DE-AC04-76DP-00789)
(DE94-001149; SAND-93-1138; CONF-9310194-1) Avail: CASI HC A02/MF A01

The high conductivity provided by solder closure joints of component housings is sometimes required to ensure electrical shielding of the components contained within. However, using a soldering iron to produce the solder joints can lead to charring of the insulating materials within the housing. To overcome this problem, the localized heating characteristics of laser soldering can be exploited. The feasibility of laser soldering Sn plated brass housings with a CW Nd:YAG laser has been investigated. It has been determined that laser soldering of these housings using a low solids solder flux is a viable technique and will minimize the amount of heat input to the enclosed electronic components. Metallographic analysis has shown good wetting of the solder on the housing components. Accelerated aging experiments indicate that no significant corrosion potential due to solder flux residues exists. Although a low solids flux was used to make the joints, initial results indicate that a fluxless technique can be developed to eliminate fluxes completely. DOE

(Contract DE-AC05-84OR-21400)
(DE94-001997; ORNL/Sub-91-SH641/1) Avail: CASI HC A04/MF A01

Absorption heat pumps have received renewed and increasing attention in the past two decades. The rising cost of electricity has made the particular features of this heat-powered cycle attractive for both residential and industrial applications. Solar-powered absorption chillers, gas-fired domestic heat pumps, and waste-heat-powered industrial temperature boosters are a few of the applications recently subjected to intensive research and development. The absorption heat pump research community has begun to search for both advanced cycles in various multistage configurations and new working fluid combinations with potential for enhanced performance and reliability. The development of working absorption systems has created a need for reliable and effective system simulations. A computer code has been developed for simulation of absorption systems at steady state in a flexible and modular form, making it possible to investigate various cycle configurations with different working fluids. The code is based on unit subroutines containing the governing equations for the system's components and property subroutines containing thermodynamic properties of the working fluids. The user conveys to the computer an image of his cycle by specifying the different subunits and their interconnections. Based on this information, the program calculates the temperature, flow rate, concentration, pressure, and vapor fraction at each state point in the system, and the heat duty at each unit, from which the coefficient of performance (COP) may be determined. This report describes the code and its operation, including improvements introduced into the present version. Simulation results are described for LiBr-H2O triple-effect cycles, LiCl-H2O solar-powered open absorption cycles, and NH3-H2O single-effect and generator-absorber heat exchange cycles. An appendix contains the user's manual. DOE

REDUCTION OF HYDROCARBON IMPURITIES IN 200 l/h HELIUM LIQUEFIER-REFRIGERATOR SYSTEM
Shuichi Yamada, Toshiyuki Mito, Arata Nishimura, Kazuya Takahata, Sadao Satoh, Junya Yamamoto, Hidemasa Yamamura (Kobe Steel Ltd., Japan.), Kaoru Masuda (Kobe Steel Ltd., Japan.), Shinichirou Kashihara (Kobe Steel Ltd., Japan.), and Katsuaki Fukusada (Kobe Steel Ltd., Japan.) et al Nov. 1993 22 p
(NIFS-259) Avail: CASI HC A03/MF A01

A cryogenic system with the capacity of 200 l/h or 500 W at 4.4 K was developed in order to supply the superconducting conductors and coils of the LHD. As a by-product of operating the cryogenic system, the impurity densities of hydrocarbon gases in the circulating helium gas became much larger than the expected values for this cryogenic system. So much larger in fact, that it became necessary to carefully monitor the operational conditions of the circulating compressor by means of gas chromatography. Impurity gas densities of oxygen, nitrogen, and ethane increased significantly when the output capacity of the compressor was reduced. In a two-stage oil injected compression system, with a variable stroke mechanism for a first stage, a reduction in the capacity of the first stage leads to a larger compression ratio for the second stage, and the temperature of the injected oil becomes higher. The production of the impurities in the helium might be caused by decomposition of the injected oil in the compressor. The compressor, therefore, was reconstructed such that the injection oil is supplied sufficiently, and the compression ratio division becomes even for each stage. It was confirmed that the impurities were not produced after the modification. Author (revised)

ACTIVE CONTROL OF BUILDINGS DURING EARTHQUAKES
Vicki L. Vance (Stanford Univ., CA.) Dec. 1993 33 p
(RTOP 585-03-11-01)
(NASA-TM-109033; NAS 1.15:109033) Avail: CASI HC A03/MF A01

The objective of this report is to provide an overview of the different types of control systems used in buildings, to discuss the problems associated with current active control mechanisms, and to show the cost-effectiveness of applying active control to buildings. In addition, a small case study investigates the feasibility and benefits of using embedded actuators in buildings. Use of embedded actuators could solve many of the current problems associated with active control by providing a wider bandwidth of control, quicker speed of response, increased reliability and reduced power requirement. Though embedded actuators have not been developed for buildings, they have previously been used in space structures. Many similarities exist between large civil and aerospace structures indicating that direct transfer of concepts between the two disciplines may be possible. In particular, much of the Controls-Structures Interaction (CSI) technology currently being developed could be beneficially applied to civil structures. While several buildings with active control systems have been constructed in Japan, additional research and experimental verification are necessary before active control systems become widely accepted and implemented. There are several methods to analyze a model. To verify invariant properties there are two kinds of invariant methods: place invariants and transition invariants. Place invariants can be used to prove properties that hold in each reachable state. A transition invariant is a characterization of (finite) traces that bring an actor back to its initial state or an equivalent one. These methods are studied in the first section. The second section considers occurrence graph methods. They are used to check if a system can reach states with certain properties. These methods are specialized in section three to study the time behavior of systems, specifically to compute throughput or response times. NTIS

NORMAL ZONE PROPAGATION AND THERMAL HYDRAULIC QUENCHBACK IN A CABLE-IN-CONDUIT SUPERCONDUCTOR
J. W. Lue and L. Dresner 1993 8 p Presented at the International Cryogenic Engineering Conference and International Cryogenic Materials Conference, Albuquerque, NM, 12-16 Jul. 1993 16 Jul. 1993
(Contract DE-AC05-84OR-21400)
(DE94-002457; CONF-930703-37) Avail: CASI HC A02/MF A01

When a local normal zone appears in a cable-in-conduit superconductor, a slug of hot helium is produced. The pressure rises and the hot helium expands. Thus, the normal zone propagation in such a conductor can be governed by the hot helium expansion, rather than the heat conduction along the conductor. The expansion of the hot helium compresses the cold helium outside of the normal zone. This raises the temperature of the cold helium. When the temperature rise reaches the current sharing limit, the superconductor in contact goes normal. Thus a rapid increase in normal zone propagation occurs. This phenomenon is termed Thermal Hydraulic Quenchback (THQ). An experiment was performed to investigate this process. The existence of THQ was verified. Thresholds of THQ were also observed by varying the conductor current, the magnetic field, the temperature, and the initial normal zone length. When THQ occurred, normal zone propagation approaching the velocity of sound was observed. A better picture of THQ is obtained by a careful comparison of the data with analytical studies. DOE

APPENDIX A: PROPOSED STATEMENT OF WORK, 1994
In its New Technologies for Space Avionics, 1993 Dec. 1993 5 p
(For primary document see N94-25193 06-31)
Avail: CASI HC A01/MF A01

This NRA effort is devoted to developing new techniques and methodologies which utilize and/or provide support to Integrated Vehicle Health Management (IVHM) concepts and techniques, modern design processes, and open architectures to realize an avionics system architecture that relieves the flight control system (FCS) of the requirement of maintaining intimate knowledge and control of the vehicle subsystems (for instance, the reaction control system (RCS)). The benefit of this architecture is that future upgrades and enhancements to the system(s) or to individual components within the system(s) are greatly simplified. This approach also allows a much more straightforward treatment of failure analysis, system diagnosis, and the design of fault containment domains. This NRA effort is also devoted to realizing capabilities to provide an available avionics system (and subsystem(s)) at minimum operational cost. This thrust provides a direct benefit to NASA in that it seeks to accelerate the design cycle to allow state of the art components and designs to actually appear in the fielded system rather than merely in the initial design. To achieve this, this effort is intended to benefit from efforts already underway at Lockheed and other major contractors. For instance, Lockheed Sanders is currently engaged in a major DoD funded development program which has the goal of cutting design cycle time of high performance electronics by a factor of four while simultaneously improving quality also by a factor of four. The early work on this program was used to enable the rapid prototyping of the Reaction Jet Drive Controller which was accomplished in 1993. Similarly, maximum leverage will be derived from recent NASA and DoD efforts to increase the content of high quality commercial grade electronic components in systems for aerospace applications. Both of these goals result in a system with enhanced cost effectiveness, increased reliability, and greatly increased performance compared to a system developed using a more conventional approach. THE CHARACTERIZATION OF REACTION-CONVECTION-DIFFUSION PROCESSES BY TRAVELLING WAVES
B. H. Gilding and R. Kersner (Hungarian Academy of Sciences, Budapest.) Jan. 1993 68 p
(MEMO-1111; ETN-94-94747) Avail: CASI HC A04/MF A01

The necessary and sufficient criterion for finite speed of propagation for the general nonlinear reaction convection diffusion equation u(sub t) (a(u))(sub xx) + (b(u))(sub x) + c(u) is determined. The assumptions on the coefficients a, b and c are such that the classification unifies and generalizes previously known results. The technique employed is comparison of an arbitrary solution of the equation with suitably constructed traveling wave solutions and subsolutions. Basically the central conclusion is that the equation exhibits finite speed of propagation if and only if it admits a traveling wave solution with bounded support. Concurrently, the search for a traveling wave solution with bonded support can be reduced to the study of a singular nonlinear integral equation whose solution must satisfy a certain constraint. ESA

Satellite-based mobile communications systems provide voice and data communications to users over a vast geographic area. The users may communicate via mobile or hand-held terminals, which may also provide access to terrestrial cellular communications services. While the first and second International Mobile Satellite Conferences (IMSC) mostly concentrated on technical advances, this Third IMSC also focuses on the increasing worldwide commercial activities in Mobile Satellite Services. Because of the large service areas provided by such systems, it is important to consider political and regulatory issues in addition to technical and user requirements issues. Topics covered include: the direct broadcast of audio programming from satellites; spacecraft technology; regulatory and policy considerations; advanced system concepts and analysis; propagation; and user requirements and applications. For individual titles, see N94-22736 through N94-22836.

WORLDWIDE SURVEY OF DIRECT-TO-LISTENER DIGITAL AUDIO DELIVERY SYSTEMS DEVELOPMENT SINCE WARC-1992
Dion D. Messer *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 3-8 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Each country was allocated frequency band(s) for direct-to-listener digital audio broadcasting at WARC-92. These allocations were near 1500, 2300, and 2600 MHz. In addition, some countries are encouraging the development of digital audio broadcasting services for terrestrial delivery only in the VHF bands (at frequencies from roughly 50 to 300 MHz) and in the medium-wave broadcasting band (AM band) (from roughly 0.5 to 1.7 MHz). The development activity increase was explosive. Current development, as of February 1993, as it is known to the author is summarized. The information given includes the following characteristics, as appropriate, for each planned system: coverage areas, audio quality, number of audio channels, delivery via satellite/terrestrial or both, carrier frequency bands, modulation methods, source coding, and channel coding. Most proponents claim that they will be operational in 3 or 4 years. Author

Personal Communications and Digital Audio Broadcasting are two new services that the European Space Agency (ESA) is investigating for future European and Global Mobile Satellite systems. ESA is active in promoting these services in their various mission options including non-geostationary and geostationary satellite systems. A Medium Altitude Global Satellite System (MAGSS) for global personal communications at L and S-band, and a Multiregional Highly inclined Elliptical Orbit (M-HEO) system for multiregional digital audio broadcasting at L-band are described. Both systems are being investigated by ESA in the context of future programs, such as Archimedes, which are intended to demonstrate the new services and to develop the technology for future non-geostationary mobile communication and broadcasting satellites. DIRECT BROADCAST SATELLITE-RADIO, SPACE-SEGMENT/RECEIVER TRADEOFFS
Nasser Golshan *In its* Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 15-20 Sponsored in part by United States Information Agency (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The balance between receiver complexity and the required satellite equivalent isotropically radiated power (EIRP) for Direct Broadcast Satellite-Radio (DBS-R) service is addressed. In general the required receiver complexity and cost can be reduced at the expense of higher space-segment cost by allowing a higher satellite EIRP. The tradeoff outcome is sensitive to the total number of anticipated receivers in a given service area, the number of audio programs, and the required audio quality. An understanding of optimum choice of satellite EIRP for DBS-R under various service requirements is a critical issue at this time when International Radio Consultative Committee (CCIR) is soliciting input in preparation for the International Telecommunications Union (ITU) planning conference for the service. The status of the ongoing Direct Broadcast Satellite-Radio (DBS-R) Receiver Development Task being performed at the Jet Propulsion Laboratory, California Institute of Technology (JPL) is reported. This work is sponsored by the Voice of America/U.S. Information Agency through an agreement with NASA. The objective of this task is to develop, build, test, and demonstrate a prototype receiver that is compatible with reception of digital audio programs broadcast via satellites. The receiver is being designed to operate under a range of reception conditions, including fixed, portable, and mobile, as well as over a sufficiently wide range of bit rates to accommodate broadcasting systems with different cost/audio quality objectives. While the requirements on the receiver are complex, the eventual goal of the design effort is to make the design compatible with low cost production as a consumer product. One solution may be a basic low cost core design suitable for a majority of reception conditions, with optional enhancements for reception in especially difficult environments. Some of the receiver design parameters were established through analysis, laboratory tests, and a prototype satellite experiment accomplished in late 1991. Many of the necessary design trades will be made during the current

simulation effort, while a few of the key design options will be incorporated into the prototype for evaluation during the planned satellite field trials.

UTILIZING A TDRS SATELLITE FOR DIRECT BROADCAST SATELLITE-RADIO PROPAGATION EXPERIMENTS AND DEMONSTRATIONS

James E. Hollansworth *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 27-32 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The NASA/VOA Direct Broadcast Satellite - Radio (DBS-R) Program will be using a NASA Tracking Data Relay Satellite (TDRS) at 62 deg West longitude to conduct live satellite S-band propagation experiments and demonstrations of satellite sound broadcasting over the next two years (1993-1994). The NASA/VOA DBS-R program has applied intensive effort to garner domestic and international support for the DBS-R concept. An S-band DBS-R allocation was achieved for Region 2 at WARC-92 held in Spain. With this allocation, the DBS-R program now needs to conduct S-band propagation experiments and systems demonstrations that will assist in the development of planning approaches for the use of Broadcast Satellite Service (Sound) frequency bands prior to the planning conference called for by WARC-92. These activities will also support receiver concept development applied to qualities ranging from AM to Monophonic FM, Stereophonic FM, Monophonic CD, and Stereophonic CD quality. Author

AERONAUTICAL AUDIO BROADCASTING VIA SATELLITE

Forrest F. Tzeng *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 33-38 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

A system design for aeronautical audio broadcasting, with C-band uplink and L-band downlink, via Inmarsat space segments is presented. Near-transparent-quality compression of 5-kHz bandwidth audio at 20.5 kbit/s is achieved based on a hybrid technique employing linear predictive modeling and transform-domain residual quantization. Concatenated Reed-Solomon/convolutional codes with quadrature phase shift keying are selected for bandwidth and power efficiency. RF bandwidth at 25 kHz per channel, and a decoded bit error rate at 10(exp -6) with E(sub b)/N(sub o) at 3.75 dB are obtained. An interleaver, scrambler, modem synchronization, and frame format were designed, and frequency-division multiple access was selected over code-division multiple access. A link budget computation based on a worst-case scenario indicates sufficient system power margins. Transponder occupancy analysis for 72 audio channels demonstrates ample remaining capacity to accommodate emerging aeronautical services. Author (revised)

THE MSAT SPACECRAFT OF TELESAT MOBILE INC. Abstract Only
c18

E. Bertenyi *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 41 (For primary document see N94-22735 06-32)
Avail: CASI HC A01/MF A06

The MSAT spacecraft of the Canadian mobile satellite operator, Telesat Mobile Inc. (TMI) is described. When launched in 1994, the large geostationary MSAT spacecraft which is currently under construction by Hughes Aircraft Co. and Spar Aerospace Ltd. will enable TMI to provide mobile and transportable communications services to its customers even in the most remote parts of the North American continent. The main elements of TMI's mobile satellite system (described in a companion paper) are the space segment and the ground segment. TMI's space segment will employ one of two nearly identical satellites, one of which will be owned and operated by TMI, the other by the U.S. mobile satellite operator, American Mobile Satellite Corporation (AMSC). The two companies are participating in a joint spacecraft procurement in order to reduce the nonrecurring costs and to ensure system compatibility between the two systems; and they have also agreed to provide in-orbit backup to each other in the event of a catastrophic satellite failure. The program status, performance requirements, main parameters, and configuration of the MSAT spacecraft are reviewed. The major features of the communications subsystem are discussed in some detail, and a brief summary is presented of the spacecraft service module. Key technology items include the L-band RF power amplifier, which must operate with a high DC to RF power efficiency and generate low intermodulation when loaded with multi-carrier signals; and the large diameter deployable L-band antenna. The development status and expected performance of these spacecraft components is examined. Author (revised)

ADAPTIVE DIGITAL BEAMFORMING FOR A CDMA MOBILE COMMUNICATIONS PAYLOAD Abstract Only

Samuel G. Munoz-Garcia and Javier Benedicto Ruiz *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 43-44 (For primary document see N94-22735 06-32)
Avail: CASI HC A01/MF A06

In recent years, Spread-Spectrum Code Division Multiple Access (CDMA) has become a very popular access scheme for mobile communications due to a variety of reasons: excellent performance in multipath environments, high scope for frequency reuse, graceful degradation near saturation, etc. In this way, a CDMA system can support simultaneous digital communication among a large community of relatively uncoordinated users sharing a given frequency band. Nevertheless, there are also important problems associated with the use of CDMA. First, in a conventional CDMA scheme, the signature sequences of asynchronous users are not orthogonal and, as the number of active users increases, the self-noise generated by the mutual interference between users considerably degrades the performance, particularly in the return link. Furthermore, when there is a large disparity in received powers - due to differences in slant range or atmospheric attenuation - the non-zero cross-correlation between the signals gives rise to the so-called near-far problem. This leads to an inefficient utilization of the satellite resources and, consequently, to a drastic reduction in capacity. Several techniques were proposed to overcome this problem, such as Synchronized CDMA - in which the signature sequences of the different users are quasi-orthogonal - and power control. At the expense of increased network complexity and user coordination, these techniques enable the system capacity to be restored by equitably sharing the satellite resources among the users. An alternative solution is presented based upon the use of time-reference adaptive digital beamforming on board the satellite. This technique enables a high number of independently steered beams to be generated from a single phased array antenna, which automatically track the desired user signal and null the unwanted interference source. In order to use a time-reference adaptive antenna in a communications system, the main challenge is to obtain a reference signal highly correlated with the desired user signal and uncorrelated with the interferences. CDMA lends itself very easily to the generation of such a reference signal, thanks to the a priori knowledge of the user's signature sequence. First, the integration of an adaptive antenna in an asynchronous CDMA system is analyzed. The adaptive antenna system can provide increased interference rejection - much higher than that afforded by the code alone - and, since CDMA is mainly interference limited, any reduction in interference converts directly and linearly into an increase in capacity. Analyses and computer simulations are presented that show how an asynchronous CDMA system incorporating adaptive beamforming can provide at least as much capacity as a synchronous system. More importantly, the proposed concept allows the near-far effect to be mitigated without requiring a tight coordination of the users in terms of transmitted power control or network synchronization. The system is extremely robust to the near-far effect because the signals reaching the satellite from directions other than that of the desired user - which are likely to have different power levels - are adaptively canceled by the antenna. Finally, a payload architecture is presented that illustrates the practical implementation of this concept. This digital payload architecture demonstrates that with the advent of high performance CMOS digital processing, the on-board implementation of complex DSP techniques - in particular Digital Beamforming - has become possible, being most attractive for Mobile Satellite Communications. ELECTRICAL PERFORMANCE OF WIRE MESH FOR SPACECRAFT DEPLOYABLE REFLECTOR ANTENNAS Abstract Only

Greg Turner *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 45 (For primary document see N94-22735 06-32)

Avail: CASI HC A01/MF A06

Mobile satellite communications systems require large, high gain antennas at the spacecraft to minimize the antenna gain and power requirements for mobile user elements. The use of a deployable reflector antenna for these applications provides a lightweight system that can be compactly stowed prior to deployment on orbit. The mesh surface material is a critical component in the deployable reflector antenna design. The mesh is required to provide the desired electrical performance as well as the mechanical properties that are necessary to deploy and maintain the reflector surface on orbit. Of particular interest in multi-channel communications applications is the generation of Passive InterModulation (PIM) products at the reflector surface that can result in interference in the receive band. Wire mesh was specifically identified by some as having a high potential for PIM generation based solely on the existence of nonpermanent metal to metal contacts at the junctions that are inherent in the mesh design. There are a number of other factors, however, that reduce the likelihood of PIM occurring at the mesh reflector surface. Experimental data presented demonstrate that mesh PIM generation is not significant for typical applications. PIM and reflectivity performance of wire mesh composed of gold plated molybdenum wire in a tricot knit are described. This type of mesh was successfully used for the deployable Single Access Antennas of the Tracking and Data Relay Satellite System. Author (revised)

ADAPTIVE ARRAY ANTENNA FOR SATELLITE CELLULAR AND DIRECT BROADCAST COMMUNICATIONS

Charles R. Horton and Kenneth Abend *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 47-52 (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

Adaptive phased-array antennas provide cost-effective implementation of large, light weight apertures with high directivity and precise beamshape control. Adaptive self-calibration allows for relaxation of all mechanical tolerances across the aperture and electrical component tolerances, providing high performance with a low-cost, lightweight array, even in the presence of large physical distortions. Beam-shape is programmable and adaptable to changes in technical and operational requirements. Adaptive digital beam-forming eliminates uplink contention by allowing a single electronically steerable antenna to service a large number of receivers with beams which adaptively focus on one source while eliminating interference from others. A large, adaptively calibrated and fully programmable aperture can also provide precise beam shape control for power-efficient direct broadcast from space. Advanced adaptive digital beamforming technologies are described for: (1) electronic compensation of aperture distortion, (2) multiple receiver adaptive space-time processing, and (3) downlink beam-shape control. Cost considerations for space-based array applications are also discussed. Author (revised)

SAW BASED SYSTEMS FOR MOBILE COMMUNICATIONS SATELLITES

R. C. Peach, N. Miller, and M. Lee *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 53-58 (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

Modern mobile communications satellites, such as INMARSAT 3, EMS, and ARTEMIS, use advanced onboard processing to make efficient use of the available L-band spectrum. In all of these cases, high performance surface acoustic wave (SAW) devices are used. SAW filters can provide high selectivity (100-200 kHz transition widths), combined with flat amplitude and linear phase characteristics; their simple construction and radiation hardness also makes them especially suitable for space applications. An overview of the architectures used in the above systems, describing the technologies employed, and the use of bandwidth switchable SAW filtering (BSSF) is given. The tradeoffs to be considered when specifying a SAW based system are analyzed, using both theoretical and experimental data. Empirical rules for estimating SAW filter performance are given. Achievable performance is illustrated using data from the INMARSAT 3 engineering model (EM) processors. Author (revised)

BROADBAND LINEARISATION OF HIGH-EFFICIENCY POWER AMPLIFIERS c33

Peter B. Kenington, Kieran J. Parsons, and David W. Bennett *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 59-64 Sponsored in part by Northern Telecom Canada Ltd. (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

A feedforward-based amplifier linearization technique is presented which is capable of yielding significant improvements in both linearity and power efficiency over conventional amplifier classes (e.g. class-A or class-AB). Theoretical and practical results are presented showing that class-C stages may be used for both the main and error amplifiers yielding practical efficiencies well in excess of 30 percent, with theoretical efficiencies of much greater than 40 percent being possible. The levels of linearity which may be achieved are required for most satellite systems, however if greater linearity is required, the technique may be used in addition to conventional pre-distortion techniques. US DOMESTIC AND INTERNATIONAL REGULATORY ISSUES c84

Lon C. Levin and Dennis C. Nash *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 67-72 (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

The U.S. domestic and international regulatory and policy milestones since 1982, when NASA filed its petition with the Federal Communications Commission (FCC) to establish the U.S. domestic Mobile Satellite Service (MSS), are described. In 1985, the FCC proposed to establish MSS services and allocate spectrum for such service. In 1986, the FCC allocated L-band spectrum for MSS. In 1987, at the Mobile World Administrative Radio Conference (MOB WARC-87), despite U.S., Canadian, and Mexican efforts, the WARC did not adopt a multi-service, generic MSS allocation. In 1989, the FCC licensed the first MSS system. After two decisions by the U.S. Court of Appeals, the FCC's licensing actions remain intact. The FCC also has permitted Comsat to provide international aeronautical and land MSS via the Inmarsat system. Inmarsat, however, may not serve the domestic U.S. market. In 1991, the FCC accepted applications for MSS systems, most of which were non-geostationary proposals, for operation in the Radiodetermination Satellite Service (RDSS) bands, and the VHF and UHF bands. In 1992, the FCC proposed rules for non-geostationary MSS systems and applied a negotiated rulemaking procedure to each. Also in 1992, the U.S. position for flexibility in existing MSS bands and for additional worldwide MSS allocations was adopted in large part at the 1992 World Administrative Radio Conference (WARC-92). INTERNATIONAL ORGANIZATIONS TO ENABLE WORLD-WIDE MOBILE SATELLITE SERVICES c84

Richard L. Anglin, Jr. *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 73-78 (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

Numbers of systems exist or have been proposed to provide world-wide mobile satellite services (MSS). Developers of these systems have formulated institutional structures they consider most appropriate for profitable delivery of these services. MSS systems provide niche services and complement traditional telecommunications networks; they are not integrated into world-wide networks. To be successful, MSS system operators must be able to provide an integrated suite of services to support the increasing globalization, interconnectivity, and mobility of business. The critical issue to enabling 'universal roaming' is securing authority to provide MSS in all of the nations of the world. Such authority must be secured in the context of evolving trends in international telecommunications, and must specifically address issues of standardization, regulation and organization. Today, only one existing organization has such world-wide authority. The question is

how proponents of new MSS systems and services can gain similar authority. Securing the appropriate authorizations requires that these new organizations reflect the objectives of the nations in which services are to be delivered.

USE OF NEGOTIATED RULEMAKING IN DEVELOPING TECHNICAL RULES FOR LOW-EARTH ORBIT MOBILE SATELLITE SYSTEMS
Leslie A. Taylor *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 79-84 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Technical innovations have converged with the exploding market demand for mobile telecommunications to create the impetus for low-earth orbit (LEO) communications satellite systems. The so-called 'Little LEO's' propose use of VHF and UHF spectrum to provide position - location and data messaging services. The so-called 'Big LEO's' propose to utilize the RDSS bands to provide voice and data services. In the United States, several applications were filed with the U.S. Federal Communications Commission (FCC) to construct and operate these mobile satellite systems. To enable the prompt introduction of such new technology services, the FCC is using innovative approaches to process the applications. Traditionally, when the FCC is faced with 'mutually exclusive' applications, e.g. a grant of one would preclude a grant of the others, it uses selection mechanisms such as comparative hearings or lotteries. In the case of the LEO systems, the FCC has sought to avoid these time-consuming approaches by using negotiated rulemakings. The FCC's objective is to enable the multiple applicants and other interested parties to agree on technical and service rules which will enable the grant of all qualified applications. With regard to the VHF/UHF systems, the Advisory Committee submitted a consensus report to the FCC. The process for the systems operating in the bands above 1 GHz involved more parties and more issues but still provided the FCC useful technical information to guide the adoption of rules for the new mobile satellite service. THE PROVISION OF SPECTRUM FOR FEEDER LINKS OF NON-GEOSTATIONARY MOBILE SATELLITES
Robert R. Bowen *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 85-90 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The possibility of sharing spectrum in the 30/20 GHz band between geostationary fixed-satellite systems and feeder-links of low-earth orbit (LEO) mobile-satellite systems is addressed, taking into account that International Telecommunications Union (ITU) Radio Regulation 2613 would be a factor in such sharing. Interference into each network in both the uplink at 30 GHz and the downlink at 20 GHz is considered. It is determined that if sharing were to take place the mobile-satellite may have to cease transmission often for intervals up to 10 seconds, may have to use high-gain tracking antennas on its spacecraft, and may find it an advantage to use code-division multiple access. An alternate solution suggested is to designate a band 50 to 100 MHz wide at 28 and 18 GHz to be used primarily for feeder links to LEO systems. Author (revised)

THE POSSIBILITIES FOR MOBILE AND FIXED SERVICES IN THE 20/30 GHz FREQUENCY BANDS Abstract Only
C. D. Hughes *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 91 (For primary document see N94-22735 06-32)
Avail: CASI HC A01/MF A06

With the wide range of services now offered by satellite communications and broadcasting and the increasing trend towards small terminal systems, the traditional distinctions between fixed and mobile services are becoming less important. In the future mobile, portable, and fixed services may well operate side by side in a hybrid manner. This trend is already apparent in Europe where extensive use is being made of the fixed service frequency allocations for broadcasting and for mobile services. Similarly many ostensibly mobile terminals are serving fixed installations. Although the immediate future of mobile satellite communications continues to lie in the L-band frequency allocations, in the longer term the 20/30 GHz frequency allocations, offer the possibility of a new beginning where the advantages of hybrid systems can be included in the overall system designs at the outset. The experience gained using 20/30 GHz within the Olympus Utilization program and the likely demands for future services to highlight the most promising avenues for future system development are addressed.

USE OF THE 30/20 GHz BAND BY MULTIPURPOSE SATELLITE SYSTEMS
Stephen McNeil, Vassilios Mimis (Communications Research Centre, Ottawa, Ontario.), Vishnu Sahay, and Robert Bowen *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 93-98 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The World Administrative Radio Conference (WARC) held in 1992 allocated the bands 19.7-20.2 GHz and 29.5-30.0 GHz to both the Mobile Satellite Service (MSS) and the Fixed Satellite Service (FSS) on a co-primary basis. An economic and flexible solution for the provision of both services is to place both payloads on one spacecraft. Some of the proposed applications of such a hybrid satellite network are described. It also examines the facility for spectrum sharing between the various applications and discusses the impact on coordination. It is concluded that the coordination process would not be more onerous than traditional FSS inter-satellite coordination. Author (revised)

TRANSPARENT DATA SERVICE WITH MULTIPLE WIRELESS ACCESS
Richard A. Dean and Allen H. Levesque (GTE Government Systems Corp., Waltham, MA.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 101-106 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The rapid introduction of digital wireless networks is an important part of the emerging digital communications scene. The introduction of Digital Cellular, LEO and GEO Satellites, and Personal Communications Services poses both a challenge and an opportunity for the data user. On the one hand wireless access will introduce significant new portable data services such as personal notebooks, paging, E-mail, and fax that will put the information age in the user's pocket. On the other hand the challenge of creating a seamless and transparent environment for the user in multiple access environments and across multiple network connections is formidable. A summary of the issues associated with developing techniques and standards that can support transparent and seamless data services is presented. The introduction of data services into the radio world represents a unique mix of RF channel problems, data protocol issues, and network issues. These problems require that experts from each of these disciplines fuse the individual technologies to support these services.

INTERNETWORKING SATELLITE AND LOCAL EXCHANGE NETWORKS FOR PERSONAL COMMUNICATIONS APPLICATIONS
Richard S. Wolff (Bell Communications Research, Inc., Morristown, NJ.) and Deborah Pinck *In its* Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 107-112 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The demand for personal communications services has shown unprecedented growth, and the next decade and beyond promise an era in which the needs for ubiquitous, transparent and personalized access to information will continue to expand in both scale and scope. The exchange of personalized information is growing from two-way voice to include data communications, electronic messaging and information services, image transfer, video, and interactive multimedia. The emergence of new land-based and satellite-based wireless networks illustrates the expanding scale and trend toward globalization and the need to establish new local exchange and exchange access services to meet the communications needs of people on the move. An important issue is to identify the roles that satellite networking can play in meeting these new communications needs. The unique capabilities of satellites, in providing coverage to large geographic

areas, reaching widely dispersed users, for position location determination, and in offering broadcast and multicast services, can complement and extend the capabilities of terrestrial networks. As an initial step in exploring the opportunities afforded by the merger of satellite-based and land-based networks, several experiments utilizing the NASA ACTS satellite and the public switched local exchange network were undertaken to demonstrate the use of satellites in the delivery of personal communications services.

POWER ATTENUATION CHARACTERISTICS AS SWITCH-OVER CRITERION IN PERSONAL SATELLITE MOBILE COMMUNICATIONS
c33
Jonathan P. Castro *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 113-118 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

A third generation mobile system intends to support communications in all environments (i.e., outdoors, indoors at home or office and when moving). This system will integrate services that are now available in architectures such as cellular, cordless, mobile data networks, paging, including satellite services to rural areas. One way through which service integration will be made possible is by supporting a hierarchical cellular structure based on umbrella cells, macro cells, micro and pico cells. In this type of structure, satellites are part of the giant umbrella cells allowing continuous global coverage, the other cells belong to cities, neighborhoods, and buildings respectively. This does not necessarily imply that network operation of terrestrial and satellite segments interconnect to enable roaming and spectrum sharing. However, the cell concept does imply hand-off between different cell types, which may involve change of frequency. Within this propsective, the present work uses power attenuation characteristics to determine a dynamic criterion that allows smooth transition from space to terrestrial networks. The analysis includes a hybrid channel that combines Rician, Raleigh and Log Normal fading characteristics. Author

INTEGRATION OF MOBILE SATELLITE AND CELLULAR SYSTEMS
Elliott H. Drucker (Drucker Associates, Kirkland, WA.), Polly Estabrook, Deborah Pinck, and Laura Ekroot *In its* Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 119-124 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

By integrating the ground based infrastructure component of a mobile satellite system with the infrastructure systems of terrestrial 800 MHz cellular service providers, a seamless network of universal coverage can be established. Users equipped for both cellular and satellite service can take advantage of a number of features made possible by such integration, including seamless handoff and universal roaming. To provide maximum benefit at lowest posible cost, the means by which these systems are integrated must be carefully considered. Mobile satellite hub stations must be configured to efficiently interface with cellular Mobile Telephone Switching Offices (MTSO's), and cost effective mobile units that provide both cellular and satellite capability must be developed. There is considerable interest among mobile satellite service providers in interworking with terrestrial networks to provide a universal global network. With such interworking, subscribers may be provided a common set of services such as those planned for the Public Switched Telephone Network (PSTN), the Integrated Services Digital Network (ISDN), and future Intelligent Networks (IN's). This paper first reviews issues in satellite interworking. Next the status and interworking plans of terrestrial mobile communications service providers are examined with early examples of mobile satellite interworking including a discussion of the anticipated evolution towards full interworking between mobile satellite and both fixed and mobile terrestrial networks. INTERWORKING AND INTEGRATION OF THE INMARSAT STANDARD-M WITH PAN-EUROPEAN GSM SYSTEM
R. Tafazolli and B. G. Evans *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 131-136 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The market demand on mobile telephone communications has been increasing since the introduction of the cellular mobile telephone systems about twelve years ago. In Europe, projections indicate a demand of about 17 million subscribers for a fully deployed Pan European system. The Pan-European GSM system is to harmonize the growth of the terrestrial mobile system. Studies conducted by the European Space Agency (ESA) indicate that even with 60-70 percent of the area being covered by the GSM, a significant traffic demand (voice and data) will still exist for areas not covered by the terrestrial systems. This demand could be satisfied by a land mobile satellite system. The satellite system is therefore seen in a complementary role rather than in competition with the terrestrial system in an integrated telecommunications network. One possible scenario may be that initially the satellite system provides services to the rural areas together with areas still not covered by the GSM system. This service area is then gradually diminished as the terrestrial system expands until an optimum point is reached where the systems co-exist optimally. The objective of this paper is to investigate the possibility of integration of a space based system, in this case Inmarsat Standard-M, with the GSM (Global System for Mobile communications). One very important advantage of incorporating GSM services in Standard-M is that it will be feasible to extend the GSM services economically worldwide, not only to land mobiles but also to aeronautical and maritime mobiles. This paper aims to depict some basic concepts related to the definition of an integrated system for mobile communications, consisting of a satellite network and a terrestrial cellular network. In particular three aspects are discussed: (1) architecture definition for the satellite network; (2) assignment strategy of the satellite channels; and (3) definition of 'internetworking procedures' between cellular and satellite network, according to the selected architecture and the satellite channel assignment strategy. HANDOVER PROCEDURES IN INTEGRATED SATELLITE AND TERRESTRIAL MOBILE SYSTEMS
G. E. Corazza, M. Ruggieri (Aquila Univ., Italy.), F. Santucci (Aquila Univ., Italy.), and F. Vatalaro *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 143-148 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The integration of satellite and terrestrial mobile systems is investigated in terms of the strategies for handover across the integrated cellular coverage. The handover procedure is subdivided into an initialization phase, where the need for issuing a handover request must be identified, and an execution phase, where the request must be satisfied, if possible, according to a certain channel assignment strategy. A modeling approach that allows the design of the parameters that influence the performance of the overall handover procedure is presented, along with a few numerical results.

MSAT AND CELLULAR HYBRID NETWORKING
Patrick W. Baranowsky, II *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 149-154 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Westinghouse Electric Corporation is developing both the Communications Ground Segment and the Series 1000 Mobile Phone for American Mobile Satellite Corporation's (AMSC's) Mobile Satellite (MSAT) system. The success of the voice services portion of this system depends, to some extent, upon the interoperability of the cellular network and the satellite communication circuit switched communication channels. This paper will describe the set of user-selectable cellular interoperable modes (cellular first/satellite second, etc.) provided by the Mobile Phone and described how they are implemented with the ground segment. Topics including roaming registration and cellular-to-satellite 'seamless' call handoff will be discussed, along with the relevant Interim Standard IS-41 Revision B Cellular Radiotelecommunications Intersystem Operations and IOS-553 Mobile Station - Land Station Compatibility Specification. TRENDS IN MOBILE SATELLITE COMMUNICATION
Klaus G. Johannsen, Mike W. Bowles, Samuel Milliken, Alan R. Cherrette, and Gregory C. Busche *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 157-162 (For primary document see N94-22735 06-32)
Avail: CASI HC A01/MF A06

Ever since the U.S. Federal Communication Commission opened the discussion on spectrum usage for personal handheld communication, the community of satellite manufacturers has been searching for an economically viable and technically feasible satellite mobile communication system. Hughes Aircraft Company and others have joined in providing proposals for such systems, ranging from low to medium to geosynchronous orbits. These proposals make it clear that the trend in mobile satellite communication is toward more sophisticated satellites with a large number of spot beams and onboard processing, providing worldwide interconnectivity. Recent Hughes studies indicate that from a cost standpoint the geosynchronous satellite (GEOS) is most economical, followed by the medium earth orbit satellite (MEOS) and then by the low earth orbit satellite (LEOS). From a system performance standpoint, this evaluation may be in reverse order, depending on how the public will react to speech delay and collision. This paper discusses the trends and various mobile satellite constellations in satellite communication under investigation. It considers the effect of orbital altitude and modulation/multiple access on the link and spacecraft design. Author

OPTIMIZING SPACE CONSTELLATIONS FOR MOBILE SATELLITE SYSTEMS
T. Roussel and J.-P. Taisant *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 163-168 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Designing a mobile satellite system entails many complex trade-offs between a great number of parameters including: capacity, complexity of the payload, constellation geometry, number of satellites, quality of coverage, etc. This paper aims at defining a methodology which tries to split the variables to give rapidly some first results. The major input considered is the traffic assumption which would be offered by the system. A first key step is the choice of the best Rider or Walker constellation geometries - with different numbers of satellites - to insure a good quality of coverage over a selected service area. Another aspect to be addressed is the possible altitude location of the constellation, since it is limited by many constraints. The altitude ranges that seem appropriate considering the spatial environment, the launch and orbit keeping policy and the feasibility of the antenna allowing sufficient frequency reuse are briefly analyzed. To support these first considerations, some 'reference constellations' with similar coverage quality are chosen. The in-orbit capacity needed to support the assumed traffic is computed versus altitude. Finally, the exact number of satellite is determined. It comes as an optimum between a small number of satellites offering a high (and costly) power margin in bad propagation situation and a great number of less powerful satellites granting the same quality of service. GEOSTATIONARY PAYLOAD CONCEPTS FOR PERSONAL SATELLITE COMMUNICATIONS
J. Benedicto, P. Rinous, I. Roberts, A. Roederer, and I. Stojkovic *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 169-174 Sponsored in part by British Aerospace Aircraft Group (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper reviews candidate satellite payload architectures for systems providing world-wide communication services to mobile users equipped with hand-held terminals based on large geostationary satellites. There are a number of problems related to the payload architecture, on-board routing and beamforming, and the design of the S-band Tx and L-band Rx antenna and front ends. A number of solutions are outlined, based on trade-offs with respect to the most significant performance parameters such as capacity, G/T, flexibility of routing traffic to beams and re-configuration of the spot-beam coverage, and payload mass and power. Candidate antenna and front-end configurations were studied, in particular direct radiating arrays, arrays magnified by a reflector and active focused reflectors with overlapping feed clusters for both transmit (multimax) and receive (beam synthesis). Regarding the on-board routing and beamforming sub-systems, analog techniques based on banks of SAW filters, FET or CMOS switches and cross-bar fixed and variable beamforming are compared with a hybrid analog/digital approach based on Chirp Fourier Transform (CFT) demultiplexer combined with digital beamforming or a fully digital processor implementation, also based on CFT demultiplexing. A SYSTEM ARCHITECTURE FOR AN ADVANCED CANADIAN WIDEBAND MOBILE SATELLITE SYSTEM
P. Takats, M. Keelty, and H. Moody *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 175-180 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

In this paper, the system architecture for an advanced Canadian ka-band geostationary mobile satellite system is described, utilizing hopping spot beams to support a 256 kbps wideband service for both N-ISDN and packet-switched interconnectivity to small briefcase-size portable and mobile terminals. An assessment is given of the technical feasibility of the satellite payload and terminal design in the post year 2000 timeframe. The satellite payload includes regeneration and on-board switching to permit single hop interconnectivity between mobile terminals. The mobile terminal requires antenna tracking and platform stabilization to ensure acquisition of the satellite signal. The potential user applications targeted for this wideband service includes: home-office, multimedia, desk-top (PC) videoconferencing, digital audio broadcasting, single and multi-user personal communications. This paper describes a novel Land Mobile Satellite System (LMSS) concept applicable to networks allowing access to a large number of gateway stations ('Hubs'), utilizing low-cost Very Small Aperture Terminals (VSAT's). Efficient operation of the Forward-Link (FL) repeater can be achieved by adopting a synchronous Code Division Multiple Access (CDMA) technique, whereby inter-code interference (self-noise) is virtually eliminated by synchronizing orthogonal codes. However, with a transparent FL repeater, the requirements imposed by the highly decentralized ground segment can lead to significant efficiency losses. The adoption of a FL On-Board Processing (OBP) repeater is proposed as a means of largely recovering this efficiency impairment. The paper describes the network architecture, the system design and performance, the OBP functions and impact on implementation. The proposed concept, applicable to a future generation of the European LMSS, was developed in the context of a European Space Agency (ESA) study contract. Author

Avail: CASI HC A02/MF A06

In the field of mobile satellite communications, a system based on low-earth-orbit satellites (LEO-SAT's) such as the Iridium system has been proposed. The LEO-SAT system is able to offer mobile telecommunication services in high-latitude areas. Rain degradation, fading and shadowing are also expected to be decreased when the system is operated at a high elevation angle. Furthermore, the propagation delay generated in the LEO-SAT system is less pronounced than that in the geostationary orbit satellite (GEO-SAT) system and, in voice services, the effect of the delay is almost negligible. We proposed a concept of a broad-band mobile satellite communication system with LEO-SAT's and Optical ISL. In that system, a fixed L-band (1.6/1.5 GHz) multibeam is used to offer narrow band service to the mobile terminals in the entire area covered by a LEO-SAT and steerable Ka-band (30/20 GHz) spot beams are used for the wide band service. In this paper, we present results of a study of LEO-SAT microwave link between a satellite and a mobile terminal for a broad-band mobile satellite communication system. First, the results of link budget calculations are presented and the antennas mounted on satellites are shown. For a future mobile antenna technology, we also show digital beamforming (DBF) techniques. DBF, together with modulation and/or demodulation, is becoming a key technique for mobile antennas with advanced functions such as antenna pattern calibration, correction, and radio interference suppression. In this paper, efficient DBF techniques for transmitting and receiving are presented. Furthermore, an adaptive array antenna system suitable for this LEO-SAT is presented. Author

In the last decade, the demand for reliable data, voice, and video satellite communication links between aircraft and ground to improve air traffic control, airline management, and to meet the growing demand for passenger communications has increased significantly. It is expected that in the near future, the spectrum required for aeronautical communication services will grow significantly beyond that currently available at L-band. In anticipation of this, JPL is developing an experimental broadband aeronautical satellite communications system that will utilize NASA's Advanced Communications Technology Satellite (ACTS) as a satellite of opportunity and the technology developed under JPL's ACTS Mobile Terminal (AMT) Task to evaluate the feasibility of using K/Ka-band for these applications. The application of K/Ka-band for aeronautical satellite communications at cruise altitudes is particularly promising for several reasons: (1) the minimal amount of signal attenuation due to rain; (2) the reduced drag due to the smaller K/Ka-band antennas (as compared to the current L-band systems); and (3) the large amount of available bandwidth. The increased bandwidth available at these frequencies is expected to lead to significantly improved passenger communications - including full-duplex compressed video and multiple channel voice. A description of the proposed broadband experimental system will be presented including: (1) applications of K/Ka-band aeronautical satellite technology to U.S. industry; (2) the experiment objectives; (3) the experiment set-up; (4) experimental equipment description; and (5) industrial participation in the experiment and the benefits. This paper describes a series of aeronautical mobile data trials conducted on small aircraft (helicopters and fixed wing) utilizing a low-speed store-and-forward mobile data service. The paper outlines the user requirements for aeronautical mobile satellite communications. 'Flight following' and improved wide-area dispatch communications were identified as high priority requirements. A 'proof-of-concept' trial in a Cessna Skymaster aircraft is described. This trial identified certain development work as essential to the introduction of commercial service including antenna development, power supply modifications and doppler software modifications. Other improvements were also proposed. The initial aeronautical mobile data service available for pre-operational (Beta) trials is outlined. Pre-operational field trials commenced in October 1992 and consisted of installations on a Gralen Communications Inc. Cessna 177 and an Aerospatiale Astar 350 series light single engine helicopter. The paper concludes with a discussion of desirable near term mobile data service developments, commercial benefits, current safety benefits and potential future applications for improved safety. ACTS MOBILE SATCOM EXPERIMENTS
Brian S. Abbe, Robert E. Frye, and Thomas C. Jedrey *In its* Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 225-230 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Over the last decade, the demand for reliable mobile satellite communications (satcom) for voice, data, and video applications has increased dramatically. As consumer demand grows, the current spectrum allocation at L-band could become saturated. For this reason, NASA and the Jet Propulsion Laboratory are developing the Advanced Communications Technology Satellites (ACTS) mobile terminal (AMT) and are evaluating the feasibility of K/Ka-band (20/30 GHz) mobile satcom to meet these growing needs. U.S. industry and government, acting as co-partners, will evaluate K/Ka-band mobile satcom and develop new technologies by conducting a series of applications-oriented experiments. The ACTS and the AMT testbed will be used to conduct these mobile satcom experiments. The goals of the ACTS Mobile Experiments Program and the individual experiment configurations and objectives are further presented. Author

COCKPIT WEATHER GRAPHICS USING MOBILE SATELLITE COMMUNICATIONS
Shashi Seth *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 231-233 (For primary document see N94-22735 06-32)
(Contract NAS1-19595)
Avail: CASI HC A01/MF A06

Many new companies are pushing state-of-the-art technology to bring a revolution in the cockpits of General Aviation (GA) aircraft. The vision, according to Dr. Bruce Holmes - the Assistant Director for Aeronautics at National Aeronautics and Space Administration's (NASA) Langley Research Center, is to provide such an advanced flight control system that the motor and cognitive skills you use to drive a car would be very similar to the ones you would use to fly an airplane. We at ViGYAN, Inc., are currently developing a system called the Pilot Weather Advisor (PWxA), which would be a part of such an advanced technology flight management system. The PWxA provides graphical depictions of weather information in the cockpit of aircraft in near real-time, through the use of broadcast satellite communications. The purpose of this system is to improve the safety and utility of GA aircraft operations. Considerable effort is being extended for research in the design of graphical weather systems, notably the works of Scanlon and Dash. The concept of providing pilots with graphical depictions of weather conditions, overlaid on geographical and navigational maps, is extremely powerful. Author

(Contract USGS-AFR-0973-P-IC-9014)
Avail: CASI HC A02/MF A06

The U.S. Geological Survey (USGS) and the U.S. Agency for International Development (USAID) are providing technical assistance to the AGRHYMET program in West Africa. AGRHYMET staff use remote sensing technology to produce satellite image maps of the Sahel region of West Africa. These image maps may show vegetation greenness, sea surface temperatures, or processed weather satellite imagery. The image maps must be distributed from the AGRHYMET Regional Center in Niger to national AGRHYMET centers in the member countries of Burkina Faso, Cape Verde, Chad, Gambia, Guinea-Bissau, Mali, Mauritania, Niger, and Senegal. After consideration of a number of land- and space-based solutions for image map distribution, the best solution was determined to be use of International Maritime Satellite Organization (INMARSAT) land-based terminals. In April 1992, a field test and proof-of-concept demonstration using land-mobile terminals produced favorable results. The USGS and USAID are setting up a wide area network using INMARSAT terminals to link the AGRHYMET sites for image data transfer. The system is in the procurement and installation phase and initial opening capability may be operational for the 1993 growing season, starting in May 1993. Author

Avail: CASI HC A01/MF A06

Over the course of the first two years of experimentation with the Advanced Communications Technology Satellite (ACTS), many different K/Ka-band applications-oriented experiments will be conducted and evaluated for their commercial viability. In addition, the technological developments and advanced systems concepts associated with the various terminals and the satellite itself will also be examined. Beyond these existing experiments and the current terminal developments, many other new and exciting experiment ideas and advanced system concepts exist. With the additional use of ACTS for the last two years of its lifetime, many of these ideas could be explored. In the mobile satellite communications arena, a particular applications-oriented concept that has yet to be developed is a maritime-mobile experiment. Applications of K/Ka-band mobile satcom technologies to the pleasure cruise industry could provide similar communications services as those that are being developed for the broadband aeronautical experiments. A second applications-oriented experiment that could be of interest is the development of a hybrid satellite-cellular system experiment. In such an experimental system, a mobile K/Ka-band satellite service would extend the coverage of the already existing cellular network. Many new system concepts and terminal developments could also be accomplished. The initial characterization of the K/Ka-band mobile satellite communications propagation channel and evaluation of the currently existing rain compensation algorithms (RCA's) could lead to a second generation RCA development that would improve the overall ACTS Mobile Terminal (AMT) performance. In addition, the development of an enhanced modem to be used with the AMT that utilizes CDMA spread spectrum would also improve the overall terminal efficiency and provide a greater commercial potential for K/Ka-band applications. Other techniques worthy of further exploration and evaluation include the development of new Doppler estimation algorithms and demodulation techniques such as pseudo-coherent demodulation. The possibility of exploring these new and exciting experiment and conceptual ideas, as well as many others, with an extended ACTS satellite lifetime, are examined. Author

EUTELTRACS: THE EUROPEAN EXPERIENCE ON MOBILE SATELLITE SERVICES
Jean-Noel Colcy and Rafael Steinhaeuser *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 261-266 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

EUTELTRACS is Europe's first commercially operated Mobile Satellite Service. Under the overall network operation of EUTELSAT, the European Telecommunications Satellite Organization, EUTELTRACS provides an integrated message exchange and position reporting service. This paper describes the EUTELTRACS system architecture, the message exchange and the position reporting services, including the result of recent analysis of message delivery time and positioning accuracy. It also provides an overview of the commercial deployment, the regulatory situation for its operation within Europe and new applications outside its target market, the international road transportation. THE ORBCOMM DATA COMMUNICATIONS SYSTEM
David C. Schoen and Paul A. Locke *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 267-272 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The ORBCOMM system is designed to provide low-cost, two-way data communications for mobile and remote users. The communications system is ideally configured for low data rate applications where communicating devices are geographically dispersed and two-way communications through terrestrial means is cumbersome and not cost effective. The remote terminals use VHF frequencies which allow for the use of very small, low-cost terminals. ORBCOMM has entered into joint development agreements with several large manufacturers of both consumer and industrial electronics to design and build the remote terminals. Based on prototype work, the estimated retail cost of these units will range from $50 to $400 depending on the complexity of the design. Starting in the fall of 1993, ORBCOMM will begin service with a demonstration network consisting of two operating satellites. By the end of 1994, a full operating network of 26 satellites, four Gateway Earth Stations, and a Network Control Center will be in place. The full constellation will provide full coverage of the entire world with greater than 94 percent communications availability for the continental U.S. This paper describes the ORBCOMM system, the technology used in its implementation, and its applications. This paper describes the implementation of the ground network to support Mobile Satellite Services (MSS). The system is designed to take advantage of a powerful new satellite series and provides significant improvements in capacity and throughput over systems in service today. The system is described in terms of the services provided and the system architecture being implemented to deliver those services. The system operation is described including examples of a circuit switched and packet switched call placement. The physical architecture is presented showing the major hardware components and software functionality placement within the hardware. Author

The Iridium system is designed to provide handheld personal communications between diverse locations around the world at any time and without prior knowledge of the location of the personal units. This paper provides an overview of the system, the services it provides, its operation, and an overview of the commercial practices and relatively high volume satellite production techniques which will make the system cost effective. A constellation of 66 satellites will provide an orbiting, spherical-shell, infrastructure for this global calling capability. The satellites act as tall cellular towers and allow convenient operation for portable handheld telephones. The system will provide a full range of services including voice, paging, data, geolocation, and fax capabilities. Motorola is a world leader in the production of high volume, high quality, reliable telecommunications hardware. One of Iridium's goals is to apply these production techniques to high reliability space hardware. Concurrent engineering, high performance work teams, advanced manufacturing technologies, and improved assembly and test methods are some of the techniques that will keep the Iridium system cost effective. Mobile, global, flexible personal communications are coming that will allow anyone to call or receive a call from/to anyplace at anytime. The Iridium system will provide communications where none exist today. This connectivity will allow increased information transfer, open new markets for various business endeavors, and in general increase productivity and development. Author

THE GLOBALSTAR MOBILE SATELLITE SYSTEM FOR WORLDWIDE PERSONAL COMMUNICATIONS
Robert A. Wiedeman and Andrew J. Viterbi (Qualcomm, Inc., San Diego, CA.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 291-296 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Loral Aerospace Corporation along with Qualcomm Inc. have developed a satellite system which offers global mobile voice and data services to and from handheld and mobile user terminals with omni-directional antennas. By combining the use of low-earth orbit (LEO) satellites with existing terrestrial communications systems and innovative, highly efficient spread spectrum techniques, the Globalstar system provides users with low-cost, reliable communications throughout the world. The Globalstar space segment consists of a constellation of 48 LEO satellites in circular orbits with 750 NM (1389 km) altitude. Each satellite communicates with the mobile users via the satellite-user links and with gateway stations. The gateway stations handle the interface between the Globalstar network and the OSTN/PLMN systems. Globalstar transceivers are similar to currently proposed digital cellular telephones in size and have a serial number that will allow the end user to make and receive calls from or to that device anywhere in the world. The Globalstar system is designed to operate as a complement to existing local, long-distance, public, private and specialized telecommunications networks. Service is primarily designed to serve the rural and thin route communications needs of consumers, government users, and private networks. Author

ODYSSEY PERSONAL COMMUNICATIONS SATELLITE SYSTEM
Christopher J. Spitzer *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 297-302 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The spectacular growth of cellular telephone networks has proved the demand for personal communications. Large regions of the world are too sparsely populated to be economically served by terrestrial cellular communications. Since satellites are well suited to this application, TRW filed with the FCC on May 31, 1993 for the Odyssey construction permit. Odyssey will provide high quality wireless communication services worldwide from satellites. These services will include: voice, data, paging, and messaging. Odyssey will be an economical approach to providing communications. A constellation of 12 satellites will be orbited in three, 55 deg. inclined planes at an altitude of 10,354 km to provide continuous coverage of designated regions. Two satellites will be visible anywhere in the world at all times. This dual visibility leads to high line-of-sight elevation angles, minimizing obstructions by terrain, trees and buildings. Each satellite generates a multibeam antenna pattern that divides its coverage area into a set of contiguous cells. The communications system employs spread spectrum CDMA on both the uplinks and downlinks. This signaling method permits band sharing with other systems and applications. Signal processing is accomplished on the ground at the satellite's 'Gateway' stations. The 'bent pipe' transponders accommodates different regional standards, as well as signaling changes over time. The low power Odyssey handset will be cellular compatible. Multipath fade protection is provided in the handset. Author

INMARSAT'S PERSONAL COMMUNICATOR SYSTEM Abstract Only
Nick Hart, Hans-C. Haugli, Peter Poskett, and K. Smith *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 303-304 (For primary document see N94-22735 06-32)
Avail: CASI HC A01/MF A06

Inmarsat has been providing near global mobile satellite communications since 1982 and Inmarsat terminals are currently being used in more than 130 countries. The terminals have been reduced in size and cost over the years and new technology has enabled the recent introduction of briefcase sized personal telephony terminals (Inmarsat-M). This trend continues and we are likely to see Inmarsat handheld terminals by the end of the decade. These terminals are called Inmarsat-P and this paper focuses on the various elements required to support a high quality service to handheld terminals. The main system elements are: the handheld terminals; the space segment with the associated orbits; and the gateways to terrestrial networks. It is both likely and desirable that personal handheld satellite communications will be offered by more than one system provider and this competition will ensure strong emphasis on service quality and cost of ownership. The handheld terminals also have to be attractive to a large number of potential users, and this means that the terminals must be small enough to fit in a pocket. Battery lifetime is another important consideration, and this coupled with radiation safety requirements limits the maximum radiated EIRP. The terminal G/T is mainly constrained by the gain of the omnidirectional antenna and the noise figure of the RF front end (including input losses). Inmarsat has examined, with the support of industry, a number of Geosynchronous (GSO), Medium Earth Orbit (MEO) and Low Earth Orbit (LEO) satellite options for the provision of a handheld mobile satellite service. This paper describes the key satellite and orbit parameters and tradeoffs which affect the overall quality of service and the space segment costing. The paper also stresses not only the importance of using and sharing the available mobile frequency band allocations efficiently, but also the key considerations affecting the choice of feeder link bands. The design of the gateways and the terrestrial network is critical to the overall viability of the service, and this paper also examines the key technical parameters associated with the Land Earth Stations (LES), which act as gateways into the Public Switched Telephone Network (PSTN). These not only include the design tradeoffs associated with the LES, but also the different terrestrial network interface options. The paper concludes with a brief description of the satellite propagation conditions associated with the use of handheld terminals. It describes how the handheld results in a number of propagation impairments which are not common to the previous measurements associated with vehicle mounted antennas. These measurements indicate that there is a complex tradeoff between link margin and the elevation angle to the satellite which has a significant impact on the space segment requirements and costing. MEASUREMENTS ON THE SATELLITE-MOBILE CHANNEL AT L AND S BANDS

H. Smith, J. G. Gardiner, and S. K. Barton *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 319-324 Sponsored by United Kingdom Radiocommunications Agency and ESA (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

An experiment is described in which measurements are made on the satellite-mobile channel at L and S bands. A light aircraft carrying a c.w. beacon is flown at elevation angles of 40, 60 and 80 degrees to a mobile receiver. The signal strength at the mobile is recorded in open, urban, suburban and tree shadowed environments. This data is then analyzed to produce statistics for the channel with respect to frequency, elevation angle, and environment. Results are presented together with a brief discussion, suggested interpretation, and conclusion. Author

An overview of two planned propagation campaigns employing land-mobile scenarios with ACTS is presented. The campaigns will be undertaken through a joint effort involving the Johns Hopkins University, Applied Physics Laboratory (APL), The University of Texas at Austin, Electrical Engineering Research Laboratory (EERL), and the NASA Lewis Research Center (NASA LeRC). Propagation campaigns are planned in Central Maryland in November 1993 (elevation angle approx. equals 40 deg.) and in Fairbanks, Alaska in June 1994 (elevation angle approx. equals 8 deg.) employing a computer controlled antenna tracking system located atop a van containing a receiver/data acquisition system. The antenna will track (in azimuth) downlink transmissions at 19.914 GHz from ACTS during the mobile propagation measurements. The major objectives of the campaigns are to measure the fade and multipath effects of trees and terrain at 20 GHz for rural and suburban scenarios and to extend existing models which were previously validated at UHF to S-Band. MEASUREMENT OF MULTIPATH DELAY PROFILE IN LAND MOBILE SATELLITE CHANNELS
Tetsushi Ikegami, Yoshiya Arakaki, Hiromitsu Wakana, and Ryutaro Suzuki (Ministry of Education, Chiba, Japan.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 331-336 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Mobile satellite communication channel has been evaluated mainly with fading statistics of signal. When bandwidth of transmitting signal becomes wider, frequency selectivity of fading becomes a significant factor of the channel. Channel characteristics, not only signal variation but multipath delay spread should be evaluated. A multipath measurement system is proposed and developed for mobile satellite applications. With this system and ETS-V satellite, multipath delay profiles are measured in various environments including Tokyo metropolis and Sapporo city at 1.5 GHz. Results show that the maximum excess delay is within 1 microsec and the maximum delay spread is 0.2 microsecs at elevation angles of 40 to 47 degrees. In wideband signal transmission of about 1 MHz and more, designers should consider the effect of selective fading due to the multipath of land mobile satellite channel. Author

R. M. Allnutt, A. Dissanayake, C. Zaks, and K. T. Lin *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 337-342 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Experiments have been undertaken at COMSAT Laboratories to determine some of the propagation effects likely to be encountered by handheld satellite communications devices. L-band pilot tones aboard geosynchronous satellites at 15 and 40 deg. elevations were used to examine diurnal signal variations measured by using a hemispherical antenna. It was found that the receiver with a hemispherical antenna suffered daily peak-to-peak signal level variations of up to 12 dB compared to only 2 to 3 dB for a receiver equipped with a directional antenna. These results were highly repeatable, and extensive tests were conducted to confirm the accuracy of the data. The results suggest that the diurnal variations were due to multipath effects caused by the motion of the satellite with respect to the receiver antenna. Noting that the orbit inclinations of the satellites used in the experiment were only on the order of 2 to 3 deg., the results also suggest a potentially serious signal variation problem for low-gain antenna-based communications systems using low earth orbit satellites, since the satellite elevation angles relative to earth change far more rapidly. Avail: CASI HC A02/MF A06

A model for the prediction of the electromagnetic field strength in an urban environment is presented. The ray model, that is based on the Uniform Theory of Diffraction (UTD), includes effects of the non-perfect conductivity of the obstacles and their surface roughness. The urban environment is transformed into a list of standardized obstacles that have various shapes and material properties. The model is capable of accurately predicting the field strength in the urban environment by calculating different types of wave contributions such as reflected, edge and corner diffracted waves, and combinations thereof. Also, antenna weight functions are introduced to simulate the spatial filtering by the mobile antenna. Communication channel parameters such as signal fading, time delay profiles, Doppler shifts and delay-Doppler spectra can be derived from the ray-tracing procedure using post-processing routines. The model has been tested against results from scaled measurements at 50 GHz and proves to be accurate. Author

PROPAGATION MODEL FOR THE LAND MOBILE SATELLITE CHANNEL IN URBAN ENVIRONMENTS
M. Sforza, G. DiBernardo (Space Engineering, Rome, Italy.), and R. Cioni (IDS Ingegneria dei Sistemi S.p.A., Pisa, Italy.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 349-354 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper presents the major characteristics of a simulation package capable of performing a complete narrow and wideband analysis of the mobile satellite communication channel in urban environments for any given orbital configuration. The wavelength-to-average urban geometrical dimension ratio has required the use of the Geometrical Theory of Diffraction (GTD). For the RF frequency range, the model has been designed to be (1 up to 60 GHz) extended to include effects of non-perfect conductivity and surface roughness. Taking advantage of the inherent capabilities of such a high frequency method, we are able to provide a complete description of the electromagnetic field at the mobile terminal. Using the information made available at the ray-tracer and GTD solver outputs, the Land Mobile Satellite (LMS) urban model can also give a detailed description of the communication channel in terms of power delay profiles, Doppler spectra, channel scattering functions, and so forth. Statistical data, e.g. cumulative distribution functions, level crossing rates or distributions of fades are also provided. The user can access the simulation tool through a Design-CAD user-friendly interface by means of which she can effectively design her own urban layout and run consequently all the envisaged routines. The software is optimized in its execution time so that numerous runs can be achieved in a considerably short time. Author (revised)

A PREDICTION MODEL OF SIGNAL DEGRADATION IN LMSS FOR URBAN AREAS
Takashi Matsudo, Kenichi Minamisono, Yoshio Karasawa, and Takayasu Shiokawa *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 355-360 (For primary document see N94-22735 06-32)
(Contract INMARSAT-92-798/BK)
Avail: CASI HC A02/MF A06

A prediction model of signal degradation in a Land Mobile Satellite Service (LMSS) for urban areas is proposed. This model treats shadowing effects caused by buildings statistically and can predict a Cumulative Distribution Function (CDF) of signal diffraction losses in urban areas as a function of system parameters such as frequency and elevation angle and environmental parameters such as number of building stories and so on. In order to examine the validity of the model, we compared the percentage of locations where diffraction losses were smaller than 6 dB obtained by the CDF with satellite visibility measured by a radiometer. As a result, it was found that this proposed model is useful for estimating the feasibility of providing LMSS in urban areas. Author (revised)

Mobile Satellite Systems (MSS) in Highly Elliptical (HEO) and circular Earth orbits at Medium (MEO) and Low (LEO) altitudes have been intensively studied in the last few years as an effective means of providing global communication services. Such global coverage MSS networks are also expected to mitigate typical channel impairments usually encountered in geostationary Land Mobile Satellite (LMS) systems. In the design stages of these satellite networks, information regarding the mobile propagation channel is needed to assess the overall link availability versus elevation angle and environmental scenarios. For multisatellite LMS configurations, the mobile user on the Earth surface sees, at any given time, more than one satellite of the constellation. In our paper, it is shown that, under certain working assumptions regarding the statistics of the propagation channel, an improvement of the link availability may be achieved through the use of a multisatellite constellation. The analyses have been carried out using the European Space Agency (ESA) LMS propagation data base which presently covers a wide range of elevation angles and environmental scenarios. SYSTEMS IMPLICATIONS OF L-BAND FADE DATA STATISTICS FOR LEO MOBILE SYSTEMS
Carrie L. Devieux *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 367-372 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper examines and analyzes research data on the role of foliage attenuation in signal fading between a satellite transmitter and a terrestrial vehicle-mounted receiver. The frequency band of measurement, called L-Band, includes the region 1610.0 to 1626.5 MHz. Data from tests involving various combinations of foliage and vehicle movement conditions clearly show evidence of fast fading (in excess of 0.5 dB per millisecond) and fade depths as great or greater than 16 dB. As a result, the design of a communications link power control that provides the level of accuracy necessary for power sensitive systems could be significantly impacted. Specific examples of this include the communications links that employ Code Division Multiple Access (CDMA) as a modulation technique. Author (revised)

In this paper, technical results obtained in the first MSBN Land mobile technical trial are reported. MSBN (Mobile Satellite Business Network) is a new program undertaken by the European Space Agency (ESA) to promote mobile satellite communication in Europe, in particular voice capability. The first phase of the MSBN system implementation plan is an experimental phase. Its purpose is to evaluate through field experiments the performance of the MSBN system prior to finalization of its specifications. Particularly, the objective is to verify in the field and possibly improve the performance of the novel satellite access technique BLQS-CDMA (Band Limited Quasi-Synchronous-Code Division Multiple Access), which is proposed as baseline for the MSBN. This paper describes some low cost approaches to coherent BPSK demodulation for mobile satellite receivers. The specific application is an Inmarsat-C Land Mobile Earth Station (LMES), but the techniques are applicable to any PSK demodulator. The techniques discussed include combined sampling and quadrature downconversion with a single A/D and novel DSP algorithms for carrier acquisition offering both superior performance and economy of DSP resources. The DSP algorithms run at 5.7 MIPS, and the entire DSP subsystem, built with commercially available parts, costs under $60 at quantity-10,000. Author (revised)

ASYNCHRONOUS TIMING AND DOPPLER RECOVERY IN DSP BASED DPSK MODEMS FOR FIXED AND MOBILE SATELLITE APPLICATIONS
B. Koblents, M. Belanger, D. Woods, and P. J. McLane *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 405-410 Sponsored by Telecommunications Research Inst. of Ontario and Natural Sciences and Engineering Research Council (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

While conventional analog modems employ some kind of clock wave regenerator circuit for synchronous timing recovery, in sampled modem receivers the timing is recovered asynchronously to the incoming data stream, with no adjustment being made to the input sampling rate. All timing corrections are accomplished by digital operations on the sampled data stream, and timing recovery is asynchronous with the uncontrolled, input A/D system. A good timing error measurement algorithm is a zero crossing tracker proposed by Gardner. Digital, speech rate (2400 - 4800 bps) M-PSK modem receivers employing Gardner's zero crossing tracker were implemented and tested and found to achieve BER performance very close to theoretical values on the AWGN channel. Nyguist pulse shaped modem systems with excess bandwidth factors ranging from 100 to 60 percent were considered. We can show that for any symmetric M-PSK signal set Gardner's NDA algorithm is free of pattern jitter for any carrier phase offset for rectangular pulses and for Nyquist pulses having 100 percent excess bandwidth. Also, the Nyquist pulse shaped system is studied on the mobile satellite channel, where Doppler shifts and multipath fading degrade the pi/4-DQPSK signal. Two simple modifications to Gardner's zero crossing tracker enable it to remain useful in the presence of multipath fading. Author (revised)

IMPROVED FRAME SYNCHRONIZATION SCHEMES FOR INMARSAT-B/M SCPC AND TDM CHANNELS
Si-Ming Pan, Randy L. Hanson, Donald H. Madill, and Paul C. Chapman *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 411-416 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper proposes faster, more robust, frame synchronization schemes for various Inmarsat-B and Inmarsat-M communication and signalling channels. Equations are developed which permit frame synchronization strategies of the type specified by Inmarsat to be evaluated in terms of average true lock time, average false maintenance time, and average search time. Evaluation o. the currently specified framing schemes shows that a significant performance improvement is obtained by optimizing the threshold parameters of the scheme. The optimization seeks a compromise between the conflicting requirements of maximizing true lock time and minimizing search time. Author (revised)

ESTIMATION OF FREQUENCY OFFSET IN MOBILE SATELLITE MODEMS
W. G. Cowley, M. Rice, and A. N. McLean *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 417-422 Sponsored by Australian Space Office and Optus Communications (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

In mobilesat applications, frequency offset on the received signal must be estimated and removed prior to further modem processing. A straightforward method of estimating the carrier frequency offset is to raise the received MPSK signal to the M-th power, and then estimate the location of the peak spectral component. An analysis of the lower signal to noise threshold of this method is carried out for BPSK signals. Predicted thresholds are compared to simulation results. It is shown how the method can be extended to pi/M MPSK signals. A real-time implementation of frequency offset estimation for the Australian mobile satellite system is described. Author

THEORETICAL AND SIMULATED PERFORMANCE FOR A NOVEL FREQUENCY ESTIMATION TECHNIQUE
Stewart N. Crozier *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 423-428 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

A low complexity, open-loop, discrete-time, delay-multiply-average (DMA) technique for estimating the frequency offset for digitally modulated MPSK signals is investigated. A nonlinearity is used to remove the MPSK modulation and generate the carrier component to be extracted. Theoretical and simulated performance results are presented and compared to the Cramer-Rao lower bound (CRLB) for the variance of the frequency estimation error. For all signal-to-noise ratios (SNR's) above threshold, it is shown that the CRLB can essentially be achieved with linear complexity. Author (revised)

A PATTERN JITTER FREE AFC SCHEME FOR MOBILE SATELLITE SYSTEMS
Shousei Yoshida *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 429-434 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper describes a scheme for pattern jitter free automatic frequency control (AFC) with a wide frequency acquisition range. In this scheme, equalizing signals fed to the frequency discriminator allow pattern jitter free performance to be achieved for all roll-off factors. In order to define the acquisition range, frequency discrimination characateristics are analyzed on a newly derived frequency domain model. As a result, it is shown that a sufficiently wide acquisition range over a given system symbol rate can be achieved independent of symbol timing errors. Additionally, computer simulation demonstrates that frequency jitter performance improves in proportion to E(sub b)/N(sub 0) because pattern-dependent jitter is suppressed in the discriminator output. These results show significant promise for applciation to mobile satellite systems, which feature relatively low symbol rate transmission with an approximately 0.4-0.7 roll-off factor. Author

A CDMA SYNCHRONISATION SCHEME
C. Soprano *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 437-442 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

CDMA (Code Division Multiple Access) is known to decrease inter-service interference in Satellite Communication Systems. Its performance is increased by chip quasi-synchronous operation which virtually eliminates the self-noise; however, the theory shows that the time error on the synchronization has to be kept at less than one tenth of a chip which, for 1 Mchip/sec. spreading rate, corresponds to 10(exp -7) sec. This, on the return-link, may only be achieved by means of a closed loop control system which, for mobile communication systems, has to be capable of autonomous operation. Until now some results have been reported on the feasibility of chip quasi-synchronous operation for mobile communication systems only including satellites on GEO (Geostationary Earth Orbit). In what follows, the basic principles are exposed, and results are presented showing how low chip synchronism error may be achieved by means of an autonomous control loop operating through satellites on any Earth orbit. A PROTOCOL FOR SATELLITE ACCESS VIA USE OF SPOT-BEAMS
Stefan Ramseier and Anthony Ephremides *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 443-448 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

In this paper, we develop a new protocol for multiple access to a GEO-satellite that utilizes an electronically-switched spot-beam. The emphasis is on an integrated voice/data protocol which takes advantage of the propagation latency and which offers centralized control with excellent delay and throughput characteristics. The protocol also allows full exploitation of the advantages of a hopping beam satellite, such as smaller earth stations and frequency re-use. Author (revised)

A HIGH QUALITY VOICE CODER WITH INTEGRATED ECHO CANCELLER AND VOICE ACTIVITY DETECTOR FOR MOBILE SATELLITE APPLICATIONS
A. M. Kondoz and B. G. Evans *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 449-454 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

In the last decade, low bit rate speech coding research has received much attention resulting in newly developed, good quality, speech coders operating at as low as 4.8 Kb/s. Although speech quality at around 8 Kb/s is acceptable for a wide variety of applications, at 4.8 Kb/s more improvements in quality are necessary to make it acceptable to the majority of applications and users. In addition to the required low bit rate with acceptable speech quality, other facilities such as integrated digital echo cancellation and voice activity detection are now becoming necessary to provide a cost effective and compact solution. In this paper we describe a CELP speech coder with integrated echo canceller and a voice activity detector all of which have been implemented on a single DSP32C with 32 KBytes of SRAM. The quality of CELP coded speech has been improved significantly by a new codebook implementation which also simplifies the encoder/decoder complexity making room for the integration of a 64-tap echo canceller together with a voice activity detector. PERFORMANCE OF THE UNIQUE-WORD-REVERSE-MODULATION TYPE DEMODULATOR FOR MOBILE SATELLITE COMMUNICATIONS
Tomohiro Dohi, Kazumasa Nitta, and Takashi Ueda *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 455-460 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper proposes a new type of coherent demodulator, the unique-word (UW)-reverse-modulation type demodulator, for burst signal controlled by voice operated transmitter (VOX) in mobile satellite communication channels. The demodulator has three individual circuits: a pre-detection signal combiner, a pre-detection UW detector, and a UW-reverse-modulation type demodulator. The pre-detection signal combiner combines signal sequences received by two antennas and improves bit energy-to-noise power density ratio (E(sub b)/N(sub 0)) 2.5 dB to yield 10(exp -3) average bit error rate (BER) when carrier power-to-multipath power ratio (CMR) is 15 dB. The pre-detection UW detector improves UW detection probability when the frequency offset is large. The UW-reverse-modulation type demodulator realizes a maximum pull-in frequency of 3.9 kHz, the pull-in time is 2.4 seconds and frequency error is less than 20 Hz. The performances of this demodulator are confirmed through computer simulations and its effect is clarified in real-time experiments at a bit rate of 16.8 kbps using a digital signal processor (DSP). SEPARABLE CONCATENATED CODES WITH ITERATIVE MAP DECODING FOR RICIAN FADING CHANNELS
J. H. Lodge and R. J. Young *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 467-472 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Very efficient signalling in radio channels requires the design of very powerful codes having special structure suitable for practical decoding schemes. In this paper, powerful codes are obtained by combining comparatively simple convolutional codes to form multi-tiered 'separable' convolutional codes. The decoding of these codes, using separable symbol-by-symbol maximum a posteriori (MAP) 'filters', is described. It is known that this approach yields impressive results in non-fading additive white Gaussian noise channels. Interleaving is an inherent part of the code construction, and consequently, these codes are well suited for fading channel communications. Here, simulation results for communications over Rician fading channels are presented to support this claim.

DIVERSITY RECEPTION FOR ADVANCED MULTI-SATELLITE NETWORKS: A CDMA APPROACH
E. Colzi, R. DeGaudenzi, C. Elia, F. Giannetti (Pisa Univ., Italy.), and R. Viola *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 473-478 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Diversity reception for Synchronous CDMA (S-CDMA) is introduced and analyzed. A Gaussian co-channel synchronous and asynchronous interference approximation is derived to evaluate the effects on the system bit error rate. Numerical results are provided for a simple mobile communication system where the signals transmitted by two distinct satellites in visibility are coherently combined by a three fingers Rake receiver. A second example showing performance of an integrated ground/satellite single frequency network for digital audio broadcasting is presented. Results show the capacity advantage of utilizing S-CDMA in combination with diversity reception. Author

SYSTEM SERVICES AND ARCHITECTURE OF THE TMI SATELLITE MOBILE DATA SYSTEM
D. Gokhale, A. Agarwal, and A. Guibord (Telesat Mobile, Inc., Ottawa, Ontario.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 479-484 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The North American Mobile Satellite Service (MSS) system being developed by AMSC/TMI and scheduled to go into service in early 1995 will include the provision for real time packet switched services (mobile data service - MDS) and circuit switched services (mobile telephony service - MTS). These services will utilize geostationary satellites which provide access to mobile terminals (MT's) through L-band beams. The MDS system utilizes a star topology with a centralized data hub (DH) and will support a large number of mobile terminals. The DH, which accesses the satellite via a single Ku band beam, is responsible for satellite resource management, for providing mobile users with access to public and private data networks, and for comprehensive network management of the system. This paper describes the various MDS services available for the users, the ground segment elements involved in the provisioning of these services, and a summary description of the channel types, protocol architecture, and network management capabilities provided within the system. A COMPARISON BETWEEN COHERENT AND NONCOHERENT MOBILE SYSTEMS IN LARGE DOPPLER SHIFT, DELAY SPREAD, AND C/I ENVIRONMENT

Kamilo Feher *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 485-490 (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

The performance and implementation complexity of coherent and of noncoherent QPSK and GMSK modulation/demodulation techniques in a complex mobile satellite systems environment, including large Doppler shift, delay spread, and low C/I, are compared. We demonstrate that for large f(sub d)T(sub b) products, where f(sub d) is the Doppler shift and T(sub b) is the bit duration, noncoherent (discriminator detector or differential demodulation) systems have a lower BER floor than their coherent counterparts. For significant delay spreads, e.g., tau(sub rms) greater than 0.4 T(sub b), and low C/I, coherent systems outperform noncoherent systems. However, the synchronization time of coherent systems is longer than that of noncoherent systems. Spectral efficiency, overall capacity, and related hardware complexity issues of these systems are also analyzed. We demonstrate that coherent systems have a simpler overall architecture (IF filter implementation-cost versus carrier recovery) and are more robust in an RF frequency drift environment. Additionally, the prediction tools, computer simulations, and analysis of coherent systems is simpler. The threshold or capture effect in low C/I interference environment is critical for noncoherent discriminator based systems. We conclude with a comparison of hardware architectures of coherent and of noncoherent systems, including recent trends in commercial VLSI technology and direct baseband to RF transmit, RF to baseband (0-IF) receiver implementation strategies. TRANSMISSION OVER EHF MOBILE SATELLITE CHANNELS

W. Zhuang, J.-Y. Chouinard, and A. Yongacoglu *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 499-504 (For primary document see N94-22735 06-32) (Grant NSERC-STR-0100720)

Avail: CASI HC A02/MF A06

Land mobile satellite communications at Ka-band (30/20 GHz) are attracting an increasing interest among researchers because of the frequency band availability and the possibility of small earth station designs. However, communications at the Ka-band pose significant challenges in the system designs due to severe channel impairments. Because only very limited experimental data for mobile applications at Ka-band is available, this paper studies the channel characteristics based on experimental data at L-band (1.6/1.5 GHz) and the use of frequency scaling. The land mobile satellite communication channel at Ka-band is modelled as log-normal Rayleigh fading channel. The first and second-order statistics of the fading channel are studied. The performance of a coherent BPSK system over the fading channel at L-band and K-band is evaluated theoretically and validated by computer simulations. Conclusions on the communication channel characteristics and system performance at L-band and Ka-band are presented. Author (revised)

ADAPTIVE DATA RATE CONTROL TDMA SYSTEMS AS A RAIN ATTENUATION COMPENSATION TECHNIQUE

Masaki Sato, Hiromitsu Wakana, Takashi Takahashi, Makoto Takeuchi, and Minoru Yamamoto *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 505-510 (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

Rainfall attenuation has a severe effect on signal strength and impairs communication links for future mobile and personal satellite communications using Ka-band and millimeter wave frequencies. As rain attenuation compensation techniques, several methods such as uplink power control, site diversity, and adaptive control of data rate or forward error correction have been proposed. In this paper, we propose a TDMA system that can compensate rain attenuation by adaptive control of transmission rates. To evaluate the performance of this TDMA terminal, we carried out three types of experiments: experiments using a Japanese CS-3 satellite with Ka-band transponders, in house IF loop-back experiments, and computer simulations. Experimental results show that this TDMA system has advantages over the conventional constant-rate TDMA systems, as resource sharing technique, in both bit error rate and total TDMA burst lengths required for transmitting given information. SATCOM SIMULATOR SPEEDS MSS DEPLOYMENT AND LOWERS COSTS

Tim Carey, Roland Hassun, and Dave Koberstein *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 511-516 (For primary document see N94-22735 06-32)

Avail: CASI HC A02/MF A06

Mobile satellite systems (MSS) are being proposed and licensed at an accelerating rate. How can the design, manufacture, and performance of these systems be optimized at costs that allow a reasonable return on investment? The answer is the use of system simulation techniques beginning early in the system design and continuing through integration, pre- and post-launch monitoring, and in-orbit monitoring. This paper focuses on using commercially available, validated simulation instruments to deliver accurate, repeatable, and cost effective measurements throughout the life of a typical mobile satellite system. A satellite communications test set is discussed that provides complete parametric test capability with a significant improvement in measurement speed for manufacturing, integration, and pre-launch and in-orbit testing. The test set can simulate actual up and down link traffic conditions to evaluate the effects of system impairments, propagation and multipath on bit error rate (BER), channel capacity and transponder and system load balancing. Using a standard set of commercial instruments to deliver accurate, verifiable measurements anywhere in the world speeds deployment, generates measurement confidence, and lowers total system cost. HANDOVER ASPECTS FOR A LOW EARTH ORBIT (LEO) CDMA LAND MOBILE SATELLITE (LMS) SYSTEM
P. Carter and M. A. Beach *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 523-528 Sponsored by Science Research Council and Roke Manor Research Ltd. (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper addresses the problem of handoff in a land mobile satellite (LMS) system between adjacent satellites in a low earth orbit (LEO) constellation. In particular, emphasis is placed on the application of soft handoff in a direct sequence code division multiple access (DS-CDMA) LMS system. Soft handoff is explained in terms of terrestrial macroscopic diversity, in which signals transmitted via several independent fading paths are combined to enhance the link quality. This concept is then reconsidered in the context of a LEO LMS system. A two-state Markov channel model is used to simulate the effects of shadowing on the communications path from the mobile to each satellite during handoff. The results of the channel simulation form a platform for discussion regarding soft handoff, highlighting the potential merits of the scheme when applied in a LEO LMS environment. Author

THE DESIGN AND NETWORKING OF DYNAMIC SATELLITE CONSTELLATIONS FOR GLOBAL MOBILE COMMUNICATION SYSTEMS
Cionaith J. Cullen, Xavier Benedicto, Rahim Tafazolli (Surrey Univ., Guildford, England.), and Barry Evans (Surrey Univ., Guildford, England.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 535-540 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Various design factors for mobile satellite systems, whose aim is to provide worldwide voice and data communications to users with hand-held terminals, are examined. Two network segments are identified - the ground segment (GS) and the space segment (SS) - and are seen to be highly dependent on each other. The overall architecture must therefore be adapted to both of these segments, rather than each being optimized according to its own criteria. Terrestrial networks are grouped and called the terrestrial segment (TS). In the SS, of fundamental importance is the constellation altitude. The effect of the altitude on decisions such as constellation design choice and on network aspects like call handover statistics are fundamental. Orbit resonance is introduced and referred to throughout. It is specifically examined for its useful properties relating to GS/SS connectivities. Author (revised)

LOW EARTH ORBIT SATELLITE/TERRESTRIAL MOBILE SERVICE COMPATIBILITY Abstract Only
R. E. Sheriff and J. G. Gardiner *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 541 (For primary document see N94-22735 06-32)
Avail: CASI HC A01/MF A06

Digital cellular mobile 'second generation' systems are now gradually being introduced into service; one such example is GSM, which will provide a digital voice and data service throughout Europe. Total coverage is not expected to be achieved until the mid '90's, which has resulted in several proposals for the integration of GSM with a geostationary satellite service. Unfortunately, because terrestrial and space systems have been designed to optimize their performance for their particular environment, integration between a satellite and terrestrial system is unlikely to develop further than the satellite providing a back-up service. This lack of system compatibility is now being addressed by system designers of third generation systems. The next generation of mobile systems, referred to as FPLMTS (future public land mobile telecommunication systems) by CCIR and UMTS (universal mobile telecommunication system) in European research programs, are intended to provide inexpensive, hand-held terminals that can operate in either satellite, cellular, or cordless environments. This poses several challenges for system designers, not least in terms of the choice of multiple access technique and power requirements. Satellite mobile services have been dominated by the geostationary orbital type. Recently, however, a number of low earth orbit configurations have been proposed, for example Iridium. These systems are likely to be fully operational by the turn of the century, in time for the implementation of FPLMTS. The developments in LEO mobile satellite service technology were recognized at WARC-92 with the allocation of specific frequency bands for 'big' LEO's, as well as a frequency allocation for FPLMTS which included a specific satellite allocation. When considering integrating a space service into the terrestrial network, LEO's certainly appear to have their attractions: they can provide global coverage, the round trip delay is of the order of tens of milliseconds, and good visibility to the satellite is usually possible. This has resulted in their detailed investigation in the European COST 227 program and in the work program of the European Telecommunications Standards Institute (ETSI). This paper will consider the system implications of integrating a LEO mobile service with a terrestrial service. Results will be presented from simulation software to show how a particular orbital configuration affects the performance of the system in terms of area coverage and visibility to a terminal for various locations and minimum elevation angle. Possible network topologies are then proposed for an integrated satellite/terrestrial network. Author (revised)

A PRACTICAL SYSTEM FOR REGIONAL MOBILE SATELLITE SERVICES
Randall Glein, Dennis Leverson, and Dean Olmstead *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 543-548 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The Regional Mobile Satellite (MSAT) concept proposes a worldwide, interconnected mobile satellite service (MSS) network in which MSAT-type satellites provide the space segment services to separate regions (i.e., one or a few countries). Using this concept, mobile communications users across entire continents can now be served by a handful of regionally controlled satellites in geostationary earth orbit (GEO). All requirements, including hand-held telephone capabilities, can be cost-effectively provided using proven technologies. While other concepts of regional or global mobile communications continue to be explored, the Hughes Regional MSAT system demonstrates the near-term viability of the GEO approach. Author (revised)

LOW COST ANTENNAS FOR MSAT VEHICULAR APPLICATIONS
L. Shafai and M. Barakat (InfoMagnetics Technologies Corp., Winnipeg, Manitoba.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 557-562 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

For Mobile MSAT applications a number of vehicular antennas have been developed that meet the program requirements. They are, however, costly to manufacture. Two antenna candidates are described here that provide adequate gain in the coverage zone and are also lower cost. One is the mast antenna that uses three or four element arrays of aquadrifilar helices. It generates omnidirectional pattern in azimuth and its beam is scanned in elevation. The second unit is a planar spiral antenna; it generates directional beams by a summation of the azimuthal modes. A variation of this antenna uses conical spirals to fulfill the same task. In both cases beam scanning is achieved by means of electronic switches rather than phase shifters, thus resulting in simpler configurations. Author (revised)

K- AND Ka-BAND MOBILE-VEHICULAR SATELLITE-TRACKING REFLECTOR ANTENNA SYSTEM FOR THE NASA ACTS MOBILE TERMINAL
Art Densmore, Vahraz Jamnejad, T. K. Wu, and Ken Woo *In its* Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 563-568 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

This paper describes the development of the K- and Ka-band mobile-vehicular satellite-tracking reflector antenna system for NASA's ACTS Mobile Terminal (AMT) project. ACTS is NASA's Advanced Communications Technology Satellites. The AMT project will make the first experimental use of ACTS soon after the satellite is operational, to demonstrate mobile communications via the satellite from a van on the road. The AMT antenna system consists of a mechanically steered small reflector antenna, using a shared aperture for both frequency bands and fitting under a radome of 23 cm diameter and 10 cm height, and a microprocessor controlled antenna controller that tracks the satellite as the vehicle moves about. The RF and mechanical characteristics of the antenna and the antenna tracking control system are discussed. Measurements of the antenna performance are presented. Author

AN ACTIVE K/Ka-BAND ANTENNA ARRAY FOR THE NASA ACTS MOBILE TERMINAL
A. Tulintseff, R. Crist, Art Densmore, and L. Sukamto *In its* Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 569-574 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

An active K/Ka-band antenna array is currently under development for NASA's ACTS Mobile Terminal (AMT). The AMT task will demonstrate voice, data, and video communications to and from the AMT vehicle in Los Angeles, California, and a base station in Cleveland, Ohio, via the ACTS satellite at 30 and 20 GHz. Satellite tracking for the land-mobile vehicular antenna system involves 'mechanical dithering' of the antenna, where the antenna radiates a fixed beam 46 deg. above the horizon. The antenna is to transmit horizontal polarization and receive vertical polarization at 29.634 plus or minus 0.15 GHz and 19.914 plus or minus 0.15 GHz, respectively. The active array will provide a minimum of 22 dBW EIRP transmit power density and a -8 dB/K deg. receive sensitivity.

MICROSTRIP MONOPULSE ANTENNA FOR LAND MOBILE COMMUNICATIONS
Q. Garcia, C. Martin, J. C. delValle (DCG Ingenieros, Madrid, Spain.), A. Jongejans (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.), P. Rinous (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.), and M. N. Travers (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 575-580 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Low cost is one of the main requirements in a communication system suitable for mass production, as it is the case for satellite land mobile communications. Microstrip technology fulfills this requirement which must be supported by a low cost tracking system design. The tradeoff led us to a prototype antenna composed of microstrip patches based on electromechanical closed-loop principle; the design and the results obtained are described. Author

ISOLATED AND COUPLED SUPERQUADRIC LOOP ANTENNAS FOR MOBILE COMMUNICATIONS APPLICATIONS
Michael A. Jensen and Yahya Rahmat-Samii *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 581-586 Sponsored in part by NSF (For primary document see N94-22735 06-32)
(Contract DAAB07-92-R-C977)
Avail: CASI HC A02/MF A06

This work provides an investigation of the performance of loop antennas for use in mobile communications applications. The analysis tools developed allow for high flexibility by representing the loop antenna as a superquadric curve, which includes the case of circular, elliptical, and rectangular loops. The antenna may be in an isolated environment, located above an infinite ground plane, or placed near a finite conducting plate or box. In cases where coupled loops are used, the two loops may have arbitrary relative positions and orientations. Several design examples are included to illustrate the versatility of the analysis capabilities. The performance of coupled loops arranged in a diversity scheme is also evaluated, and it is found that high diversity gain can be achieved even when the antennas are closely spaced. Author

L-BAND MOBILE TERMINAL ANTENNAS FOR HELICOPTERS
T. K. Wu, K. Farazian, N. Golshan, D. Divsalar, and S. Hinedi *In its* Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 587-592 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

The feasibility of using a low gain antenna (LGA) as a mobile terminal antenna for a helicopter is described in this paper. The objectives are to select the lowest cost antenna system which can be easily mounted on a helicopter and capable of communicating with a satellite, and to determine the best antenna position on the helicopter to mitigate the signal blockage due to rotor blades and the multipath effect from the helicopter's body. The omnidirectional LGA is selected because it is simple, reliable, and low cost. The helix antenna is selected among the many LGA's because it is the most economical one and has the widest elevation beamwidth. Both 2-arm and 4-arm helices are studied experimentally to determine the antenna's performance and the scattering effects from the helicopter's body. It is found that the LGA should be located near the tail section and at least eight inches above the helicopter. Author (revised)

AERONAUTICAL SATELLITE ANTENNA STEERING USING MAGNETIC FIELD SENSORS
John Sydor and Martial Dufour *In* JPL, Proceedings of the Third International Mobile Satellite Conference (IMSC 1993) 1993 p 593-598 (For primary document see N94-22735 06-32)
Avail: CASI HC A02/MF A06

Designers of aeronautical satellite terminals are often faced with the problem of steering a directive antenna from an airplane or helicopter. This problem is usually solved by using aircraft orientation information derived from inertial sensors on-board the aircraft in combination with satellite ephemeris information calculated from geographic coordinates. This procedure works well but relies heavily on avionics that are external to the terminal. For the majority of small aircraft and helicopters which will form the bulk of future aeronautical satcom users, such avionics either do not exist or are difficult for the satellite terminal to interface with. At the Communications Research Center (CRC), work has been undertaken to develop techniques that use the geomagnetic field and satellite antenna pointing vectors (both of which are stationary in a local geographical area) to track the position of a satellite relative to a moving platform such as an aircraft. The performance of this technique is examined and a mathematical steering transformation is developed within this paper. Details are given regarding the experimental program that will be undertaken to test the concepts proposed herein. Author

RIGOROUS ANALYSIS OF THICK MICROSTRIP ANTENNAS AND WIRE ANTENNAS EMBEDDED IN A SUBSTRATE

A. B. Smolders Jul. 1992 73 p
(EUT-92-E-263; ISBN-9-06-144263-X; ETN-94-94770) Avail: CASI HC A04/MF A01

An efficient and rigorous method for the analysis of electrically thick rectangular microstrip antennas and wire antennas with a dielectric cover is presented. The method of moments is used in combination with the exact spectral domain Green's function in order to find the unknown currents on the antenna. The microstrip antenna is fed by a coaxial cable. A proper model of the feeding coaxial structure is used. In addition, a special attachment mode was applied to ensure continuity of current at the patch-coax transition. The efficiency of the method of moments is improved by using the so called source term extraction technique, where a great part of the infinite integrals involved with the method of moment formulation is calculated analytically. Computation time can be saved by selecting a set of basis functions that describes the current distribution on the patch and probe in an accurate way using only a few terms of this set. Thick microstrip antennas have broadband characteristics. However, a proper match to 50 Ohms is often difficult. This matching problem can be avoided by using a slightly different excitation structure. The patch is now electromagnetically coupled to the feeding probe. A bandwidth of more than 40 can easily be obtained for this type of microstrip antenna. The price to be paid is a degradation of the radiation characteristics. ESA

MAKING GOVERNMENT WORK: ELECTRONIC DELIVERY OF FEDERAL SERVICES

Sep. 1993 185 p
(OTA-TCT-578; ISBN-0-16-042080-6) Avail: CASI HC A09/MF A02; SOD HC

Federal, State, and local governments face the challenge of delivering better services faster and at less cost at a time when demand is growing and budgets are tighter. Computer and telecommunication technologies offer a number of near-term opportunities for delivering Federal services electronically in partnership with State/local agencies and the private sector. To assure that these technologies benefit all citizens - not just the affluent and highly educated - will require Congress to pay special attention to policy and oversight. It will also require agencies to be innovative and skillful in introducing new electronic delivery systems. The Office of Technology Assessment's (OTA's) assessment of electronic service delivery was requested by Senator John Glenn, Chairman, Senate Committee on Governmental Affairs. This report provides Congress with alternative strategies for improving the performance of government by using modern information technologies. The report offers new perspectives to Congress as it considers reauthorizing the Paperwork Reduction Act and responds to the Administration's 'National Performance Review' and 'National Information Infrastructure' initiatives. More broadly, the report will contribute to the public debate over the role of information technology in reinventing government. Author (revised)

PHASE LINEARITY OF THE 914H COUPLED-CAVITY TRAVELING WAVE TUBE Final Report

Frank E. Kavanagh Jan. 1994 52 p
(Contract NAS3-25776; RTOP 506-72-00)
(NASA-CR-191056; E-7830; NAS 1.26:191056) Avail: CASI HC A04/MF A01

Tests of phase deviation from linearity were made on two 914H coupled-cavity traveling wave tubes (TWT). One tube had a voltage standing wave ratio (VSWR) of 2.4 and the other 1.4. The data showed that phase deviation is primarily a function of the amplitude and shape of the output VSWR. It was predicted that the low-VSWR tube would give a better system performance than the tube with a high VSWR. This prediction was confirmed by the Advanced Communications Technology Satellite (ACTS) system tests performed at the NASA Lewis Research Center. A possible improvement in the construction and stability of coupled-cavity TWT's is discussed. Author (revised)

This quarterly publication provides archival reports on developments in programs managed by JPL's Office of Telecommunications and Data Acquisition (TDA). In space communications, radio navigation, radio science, and ground-based radio and radar astronomy, it reports on activities of the Deep Space Network (DSN) in planning, supporting research and technology, implementation, and operations. Also included are standards activity at JPL for space data and information systems and reimbursable DSN work performed for other space agencies through NASA. The papers included in this document cover satellite tracking and ground-based navigation, spacecraft-ground communications, and optical communication systems for the Deep Space Network. For individual titles, see N94-23257 through N94-23269.

A REVIEW OF GPS-BASED TRACKING TECHNIQUES FOR TDRS ORBIT DETERMINATION c13

B. J. Haines, S. M. Lichten, R. P. Malla, and S.-C. Wu *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 1-16
(For primary document see N94-23256 06-32)
(RTOP 310-10-61-92-01)
Avail: CASI HC A03/MF A02

This article evaluates two fundamentally different approaches to the Tracking and Data Relay Satellite (TDRS) orbit determination utilizing Global Positioning System (GPS) technology and GPS-related techniques. In the first, a GPS flight receiver is deployed on the TDRS. The TDRS ephemerides are determined using direct ranging to the GPS spacecraft, and no ground network is required. In the second approach, the TDRS's broadcast a suitable beacon signal, permitting the simultaneous tracking of GPS and Tracking and Data Relay Satellite System satellites by ground receivers. Both strategies can be designed to meet future operational requirements for TDRS-II orbit determination. Author

NEW APPROACHES FOR TRACKING EARTH ORBITERS USING MODIFIED GPS GROUND RECEIVERS c13

S. M. Lichten, L. E. Young, S. Nandi, B. J. Haines, C. E. Dunn, and C. D.

Edwards *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 17-31 (For primary document see N94-23256 06-32)
(RTOP 310-10-61-92-91)
Avail: CASI HC A03/MF A02

A Global Positioning System (GPS) flight receiver provides a means to precisely determine orbits for satellites in low to moderate altitude orbits. Above a 5000-km altitude, however, relatively few GPS satellites are visible. New approaches to orbit determination for satellites at higher altitudes could reduce DSN antenna time needed to provide navigation and orbit determination support to future missions. Modification of GPS ground receivers enables a beacon from the orbiter to be tracked simultaneously with GPS data. The orbit accuracy expected from this GPS-like tracking (GLT) technique is expected to be in the range of a few meters or better for altitudes up to 100,000 km with a global ground network. For geosynchronous satellites, however, there are unique challenges due to geometrical limitations and to the lack of strong dynamical signature in tracking data. We examine two approaches for tracking the Tracking and Data Relay Satellite System (TDRSS) geostationary orbiters. One uses GLT with a global network; the other relies on a small 'connected element' ground network with a distributed clock for short-baseline differential carrier phase (SB Delta Phi). We describe an experiment planned for late 1993, which will combine aspects of both GLT and SB Delta Phi, to demonstrate a new approach for tracking the Tracking and Data Relay Satellites (TDRSs) that offers a number of operationally convenient and attractive features. The TDRS demonstration will be in effect a proof-of-concept experiment for a new approach to tracking spacecraft which could be applied more generally to deep-space as well as near-Earth regimes. IMPROVED THERMAL FORCE MODELING FOR GPS SATELLITES c18
Y. Vigue, R. E. Schutz (Texas Univ., Austin.), and P. A. M. Abusali (Texas Univ., Austin.) *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 32-41 (For primary document see N94-23256 06-32)
(RTOP 310-10-61-84-02)
Avail: CASI HC A02/MF A02

Geophysical applications of the Global Positioning System (GPS) require the capability to estimate and propagate satellite orbits with high precision. An accurate model of all the forces acting on a satellite is an essential part of achieving high orbit accuracy. Methods of analyzing the perturbation due to thermal radiation and determining its effects on the long-term orbital behavior of GPS satellites are presented. The thermal imbalance force, a nongravitational orbit perturbation previously considered negligible, is the focus of this article. The earth's shadowing of a satellite in orbit causes periodic changes in the satellite's thermal environment. Simulations show that neglecting thermal imbalance in the satellite force model gives orbit error larger than ten meters over several days for eclipsing satellites. This orbit mismodeling can limit accuracy in orbit determination and in estimation of baselines used for geophysical applications. Author (revised)

EXPERIMENTAL MODIFICATION AND IDENTIFICATION OF THE DSS-13 ANTENNA CONTROL SYSTEM MODEL c37
C. S. Racho and W. K. Gawronski *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 42-53 (For primary document see N94-23256 06-32)
(RTOP 310-20-65-63-00)
Avail: CASI HC A03/MF A02

This work is the first step toward increasing the bandwidth of the DSS-13 antenna position loop controller. A wider bandwidth of the controller allows for faster tracking rates and better pointing performance under windy conditions. To achieve this goal, the antenna control system model has to be improved, such that it will accurately reflect the dynamic properties of the antenna. The existing analytical model, due to its many uncertainties, could not be used in the design of the controller. However, by using experimental data, the analytical model is modified and improved, and a new model is obtained through system identification techniques. Author

PERFORMANCE OF THE X-/Ka/KABLE-BAND DICHROIC PLATE IN THE DSS-13 BEAM WAVEGUIDE ANTENNA
J. C. Chen, P. H. Stanton, and H. F. Reilly *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 54-64 (For primary document see N94-23256 06-32)
(RTOP 310-20-64-83-02)
Avail: CASI HC A03/MF A02

The first Ka-band downlink demonstration was recently carried out by the Ka-Band Link Experiment (KABLE) in association with the Mars Observer spacecraft. In order to support the mission, a dichroic plate was required in the DSS-13 beam waveguide antenna to allow simultaneous X- and Ka-band operation. An X-/ Ka-/ KABLE-band dichroic plate was designed to transmit Ka-band downlink (31.8-32.3 GHz), Ka-band uplink (34.2-34.7 GHz), and KABLE (33.6-33.8 GHz) frequencies, while reflecting X-band (8.4-8.5 GHz). A computer program was developed for the analysis of a dichroic plate with rectangular apertures by using the mode-matching method. The plate was then fabricated and tested. The reflection, group delay, and noise temperature in the antenna system due to the dichroic plate were measured. The experimental results show good agreement with theoretical prediction. Author

ANALYSIS OF OPEN-LOOP CONICAL SCAN POINTING ERROR AND VARIANCE ESTIMATORS
L. S. Alvarez *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 81-90 (For primary document see N94-23256 06-32)
(RTOP 310-20-65-63-00)
Avail: CASI HC A02/MF A02

General pointing error and variance estimators for an open-loop conical scan (conscan) system are derived and analyzed. The conscan algorithm is modeled as a weighted least-squares estimator whose inputs are samples of receiver carrier power and its associated measurement uncertainty. When the assumptions of constant measurement noise and zero pointing error estimation are applied, the variance equation is then strictly a function of the carrier power to uncertainty ratio and the operator selectable radius and period input to the algorithm. The performance equation is applied to a 34-m mirror-based beam-waveguide conscan system interfaced with the Block V Receiver Subsystem tracking a Ka-band (32-GHz) downlink. It is shown that for a carrier-to-noise power ratio greater than or equal to 30 dB-Hz, the conscan period for Ka-band operation may be chosen well below the current DSN minimum of 32 sec. The analysis presented forms the basis of future conscan work in both research and development as well as for the upcoming DSN antenna controller upgrade for the new DSS-24 34-m beam-waveguide antenna. SPUR-REDUCED DIGITAL SINUSOID SYNTHESIS

M. J. Flanagan and G. A. Zimmerman *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 91-104 (For primary document see N94-23256 06-32)
(RTOP 310-30-70-87-02)
Avail: CASI HC A03/MF A02

This article presents and analyzes a technique for reducing the spurious signal content in digital sinusoid synthesis. Spurious-harmonic (spur) reduction is accomplished through dithering both amplitude and phase values prior to word-length reduction. The analytical approach developed for analog quantization is used to produce new bounds on spur performance in these dithered systems. Amplitude dithering allows output word-length reduction without introducing additional spurs. Effects of periodic dither similar to those produced by a pseudonoise (PN) generator are analyzed. This phase-dithering method provides a spur reduction of 6(M plus one) dB per phase bit when the dither consists of M uniform variates. While the spur reduction is at the expense of an increase in system noise, the noise power can be made white, making the power spectral density small. This technique permits the use of a smaller number of phase bits addressing sinusoid lookup tables, resulting in an exponential decrease in system complexity. Amplitude dithering allows the use of less complicated multipliers and narrower data paths in purely digital applications, as well as the use of coarse resolution, highly linear digital to analog converters (DAC's) to obtain spur performance limited by the DAC linearity rather than its resolution. BOX CODES OF LENGTHS 48 AND 72
G. Solomon and Y. Jin (California Inst. of Tech., Pasadena.) *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 105-109 (For primary document see N94-23256 06-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A01/MF A02

A self-dual code length 48, dimension 24, with Hamming distance essentially equal to 12 is constructed here. There are only six code words of weight eight. All the other code words have weights that are multiples of four and have a minimum weight equal to 12. This code may be encoded systematically and arises from a strict binary representation of the (8,4;5) Reed-Solomon (RS) code over GF (64). The code may be considered as six interrelated (8,7;2) codes. The Mattson-Solomon representation of the cyclic decomposition of these codes and their parity sums are used to detect an odd number of errors in any of the six codes. These may then be used in a correction algorithm for hard or soft decision decoding. A (72,36;15) box code was constructed from a (63,35;8) cyclic code. The theoretical justification is presented herein. A second (72,36;15) code is constructed from an inner (63,27;16) Bose Chaudhuri Hocquenghem (BCH) code and expanded to length 72 using box code algorithms for extension. This code was simulated and verified to have a minimum distance of 15 with even weight words congruent to zero modulo four. The decoding for hard and soft decision is still more complex than the first code constructed above. Finally, an (8,4;5) RS code over GF (512) in the binary representation of the (72,36;15) box code gives rise to a (72,36;16*) code with nine words of weight eight, and all the rest have weights greater than or equal to 16. INTEGER COSINE TRANSFORM COMPRESSION FOR GALILEO AT JUPITER: A PRELIMINARY LOOK
L. Ekroot, S. Dolinar, and K.-M. Cheung *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 110-123 (For primary document see N94-23256 06-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A03/MF A02

The Galileo low-gain antenna mission has a severely rate-constrained channel over which we wish to send large amounts of information. Because of this link pressure, compression techniques for image and other data are being selected. The compression technique that will be used for images is the integer cosine transform (ICT). This article investigates the compression performance of Galileo's ICT algorithm as applied to Galileo images taken during the early portion of the mission and to images that simulate those expected from the encounter at Jupiter. Avail: CASI HC A03/MF A02

This article describes the approach, results, and lessons learned from an applied research project demonstrating how artificial intelligence (AI) technology can be used to improve Deep Space Network operations. Configuring antenna and associated equipment necessary to support a communications link is a time-consuming process. The time spent configuring the equipment is essentially overhead and results in reduced time for actual mission support operations. The NASA Office of Space Communications (Code O) and the NASA Office of Advanced Concepts and Technology (Code C) jointly funded an applied research project to investigate technologies which can be used to reduce configuration time. This resulted in the development and application of AI-based automated operations technology in a prototype system, the Link Monitor and Control Operator Assistant (LMC OA). The LMC OA was tested over the course of three months in a parallel experimental mode on very long baseline interferometry (VLBI) operations at the Goldstone Deep Space Communications Center. The tests demonstrated a 44 percent reduction in pre-calibration time for a VLBI pass on the 70-m antenna. Currently, this technology is being developed further under Research and Technology Operating Plan (RTOP)-72 to demonstrate the applicability of the technology to operations in the entire Deep Space Network. BEAM-WAVEGUIDE ANTENNA SERVO DESIGN ISSUES FOR TRACKING LOW EARTH-ORBITING SATELLITES **c37**
W. K. Gawronski and J. A. Mellstrom *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 135-152 (For primary document see N94-23256 06-32)
(RTOP 314-30-50-12-80)
Avail: CASI HC A03/MF A02

Upcoming NASA missions will require tracking of low-orbit satellites. As a consequence, NASA antennas will be required to track satellites at higher rates than for the current deep space missions. This article investigates servo design issues for the 34-m beam-waveguide antennas that track low-orbit satellites. This includes upgrading the servo with a feedforward loop, using a monopulse controller design, and reducing tracking errors through either proper choice of elevation pinion location, application of a notch filter, or adjustment of the elevation drive amplifier gain. Finally, improvement of the signal-to-noise ratio through averaging of the over-sampled monopulse signal is described. Author

OPTICAL SUBNET CONCEPTS FOR THE DEEP SPACE NETWORK
K. Shaik, D. Wonica, and M. Wilhelm *In its* The Telecommunications and Data Acquisition Report 15 Nov. 1993 p 153-181 (For primary document see N94-23256 06-32)
(Contracts JPL-958733; JPL-958734; RTOP 315-91-30-20-03)
Avail: CASI HC A03/MF A02

This article describes potential enhancements to the Deep Space Network, based on a subnet of receiving stations that will utilize optical communications technology in the post-2010 era. Two optical subnet concepts are presented that provide full line-of-sight coverage of the ecliptic, 24 hours a day, with high weather availability. The technical characteristics of the optical station and the user terminal are presented, as well as the effects of cloud cover, transmittance through the atmosphere, and background noise during daytime or nighttime operation on the communications link. In addition, this article identifies candidate geographic sites for the two network concepts and includes a link design for a hypothetical Pluto mission in 2015. Author

SYSTEM IDENTIFICATION USING A WAVELET-BASED APPROACH
D. A. Schoenwald 1993 3 p Presented at the 32nd Institute of Electrical and Electronic Engineers (IEEE) Conference on Decision and Control, San Antonio, TX, Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-002191; CONF-931233-2) Avail: CASI HC A01/MF A01

In this paper, an approach to system identification using the wavelet transform is outlined. The method is based on system identification algorithms that belong to the class of modulating function methods. In particular, the Pearson-Lee method is modified to make use of wavelet basis functions which provide a more precise time window to process the plant input-output data. It is proposed here that replacing these modulating functions with wavelet basis functions will provide data filtering which is less sensitive to noise and initial conditions. DOE

SOURCE SPACING IN B-ISDN
Finn Arve Aagesen 22 Dec. 1992 34 p See also PB93-162618 and PB93-162634
(PB93-201747; STF40-A92145) Avail: CASI HC A03/MF A01

A vital part of the future high capacity networks seems to be B-ISDN based on ATM. Flow management is the set of functions related to the control of the traffic flow from the applications during information transfer. Flow management is considered within the context of the user - user flow, the user - transport system flow, the transport system internal flow, the transport - ATM system flow and the ATM system internal flow. Flow management must be related to specific time resolution regions. The extreme, burst, frame, average, packet, message, and stretching interval time resolution regions are defined. The report proposes a total flow management scheme. The basic principle has been to adapt the flow management to the pattern of the applications. Such an adaption is possible by using transport system flow management mechanisms that reflect the application flow parameters and a formally defined ATM system service that makes important flow parameters visible for the ATM system. The ATM system internal flow management comprises three mechanisms: spacing, rate-control-based policing and stop-and-wait flow control. Spacing schemes based on stretching are proposed for the various transport system service classes. NTIS

NASA and the National Science Foundation (NSF) commissioned a panel of US experts to study the international status of satellite communications systems and technology. The study covers emerging systems concepts, applications, services, and the attendant technologies. The panel members travelled to Europe, Japan, and Russia to gather information first-hand. They visited 17 sites in Europe, 20 sites in Japan, and four in Russia. These included major manufacturers, government organizations, service providers, and associated R&D facilities. The panel's report was reviewed by the sites visited, by the panel, and by representatives of US industry. The report details the information collected and compares it to US activities. This is Volume 1 (Analytical Chapters) of the final report of the NASA/NSF Panel Satellite Communications Systems and Technology. The panel surveyed advanced technology being developed for commercial use in the satellite communications field in Europe, Japan, and Russia. All aspects of satellite communications were considered, including fixed, broadcast, mobile, personal communications, navigation, low earth orbit, and small satellites. The focus was on experimental and advanced technology being developed in R&D and demonstration programs rather than on today's production capabilities. Focus was on commercial satellite technology, and does not review defense-related or other confidential satellite communications capabilities. The NASA/NSF panel concluded that the United States has lost its leading position in many critical satellite communications technologies. Although U.S. industry retains a leading position in today's marketplace for satellite communications systems and services, this position is largely founded on technologies and capabilities developed in the 1960's and 1970's. Because the United States is losing ground with respect to a wide range of technologies and systems that will be key to future communications markets, the market share of the U.S. satellite communications industry is at risk. RESEARCH FOR ELECTRIC ENERGY SYSTEMS Annual Report
W. E. Anderson, ed. Oct. 1993 38 p
(DE94-001839; NISTIR-5268) Avail: CASI HC A03/MF A01

This report documents the technical progress in the two investigations which make up the project 'Support of Research Projects for Electrical Energy Systems,' Department of Energy Task Order Number 137, funded by the US Department of Energy and performed by the Electricity Division of the National Institute of Standards and Technology (NIST). The first investigation is concerned with the measurement of magnetic fields in support of epidemiogical and in vitro studies of biological field effects. During 1992, the derivation of equations which predict differences between the average magnetic flux density using circular coil probes and the flux density at the center of the probe, assuming a dipole magnetic field, were completed. The information gained using these equations allows the determination of measurement uncertainty due to probe size when magnetic fields from many electrical appliances are characterized. Consultations with various state and federal organizations and the development of standards related to electric and magnetic field measurements continued. The second investigation is concerned with two different activities related to compressed-gas insulated high voltage systems: the measurement of dissociative electron attachment cross sections and negative ion production in S2F10, S2OF10, and S2O2F10, and Monte-Carlo simulations of ac-generated partial-discharge pulses that can occur in SF6-insulated power systems and can be sources of gas decomposition. COMPATIBILITY RELATIONS AND THE FINITE-ELEMENT FORMULATION OF ELECTROMAGNETIC FIELD PROBLEMS

G. Mur 1993 5 p

(PB94-110996; ET/EM-1993-01) Copyright Avail: CASI HC A01/MF A01

When computing an electromagnetic field using the finite element method, it is possible that, although Maxwell's equations are discretized accurately, highly inaccurate computational results are obtained. In those cases it can easily be shown that (some of) the electromagnetic compatibility relations (field properties that follow from Maxwell's equations) are not satisfied. The divergence condition on the fluxes, for instance, follows directly from the field equations but not necessarily from their discretized counterparts. This necessitates inclusion of the compatibility relations in the finite-element formulation of the field problem. A survey is given of all electromagnetic compatibility relations. NTIS

ELECTROMAGNETIC SCATTERING BY INHOMOGENEOUS OBJECTS. SOLUTION METHODS BASED UPON RECIPROCITY THEOREMS OF TIME-CONVOLUTION AND TIME-CORRELATION TYPE

R. Remis 1993 64 p

(PB94-111010; ET/EM-1993-02) Copyright Avail: CASI HC A04/MF A01

The standard method for the solution of the problem of scattering of an electromagnetic wave by an inhomogeneous object is the domain-integral equation formulation. This domain-integral equation is obtained from an appropriate application of Lorentz' reciprocity theorem of the convolution type. A domain-integral equation based upon Lorentz' reciprocity theorem of the correlation type was obtained. Both types of Lorentz' reciprocity theorem were applied to a one-dimensional slab with dielectric contrast only. It is shown that it is possible to recover the domain-integral equation of the convolution type from the domain-integral equation of the correlation type. Further, the domain-integral equation of the correlation type can be manipulated into a form which is interesting to investigate numerically in the future. NTIS

FEMAX FINITE-ELEMENT PACKAGE FOR COMPUTING THREE-DIMENSIONAL TIME-DOMAIN ELECTROMAGNETIC FIELDS IN INHOMOGENEOUS MEDIA

G. Mur 1993 12 p

(PB94-111093; ET/EM-1993-11) Copyright Avail: CASI HC A03/MF A01

An efficient and accurate finite-element package is described for computing transient as well as time-harmonic three-dimensional electromagnetic fields in inhomogeneous media. For the expansion of the field in an inhomogeneous configuration, edge elements are used along the interfaces between media with different medium properties to allow for the continuity conditions of the field across these interfaces, nodal elements are used in the remaining homogeneous subdomains. In the domain of computation the package decides locally what type of element has to be used for obtaining the user-specified accuracy of modeling the field. In this way optimum results are obtained both in regard to computational efficiency and in regard to desired accuracy. The electromagnetic compatibility relations are implemented for avoiding spurious solutions. NTIS

CALIBRATION BLOCK FOR DIGITAL BEAM FORMING ANTENNA [KALIBRERINGSENHET FOER ANTENNER MED DIGITAL LOBFORMNING]

J. Piotr Starski Feb. 1993 37 p See also PB92-122670, PB92-195429 and AD-A200030 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB93-204550; FOA-C-30700-8.4; FOA-C-30700-3.2) Avail: CASI HC A03

Future communication and radar systems will require antennas with capabilities to steer the beam by electronic means. In the older antenna systems the beamforming function was performed by shaping a reflector into a desired form. The result was a good electrical performance, but the system was slow, clumsy, and could follow only one target at the same time. The present systems use computer controlled digital phase shifters (i.e. the phase shift is controlled in steps, by smallest increment, corresponding to the smallest phase shifter bit). By using an all digital beam former for a phased array antenna, the problems with phase and amplitude accuracy in the beam forming network can be virtually eliminated. This is achieved by maintaining the phase and amplitude information in each antenna element channel separately. It is very important to know the transmission data for each channel separately. This is done by including in the system a calibration network. A calibration circuit for a digital beam forming antenna is described. The circuit is designed in stripline technology and consists of a combination of couplers and power dividers. NTIS

An eye safe, compact, solid state lidar for profiling atmospheric cloud and aerosol scattering is disclosed. The transmitter of the micro pulse lidar is a diode pumped micro-J pulse energy, high repetition rate Nd:YLF laser. Eye safety is obtained through beam expansion. The receiver employs a photon counting solid state Geiger mode avalanche photodiode detector. Data acquisition is by a single card multichannel scaler. Daytime background induced quantum noise is controlled by a narrow receiver field-of-view and a narrow bandwidth temperature controlled interference filter. Dynamic range of the signal is limited to optical geometric signal compression. Signal simulations and initial atmospheric measurements indicate that micropulse lider systems are capable of detecting and profiling all significant cloud and aerosol scattering through the troposphere and into the stratosphere. The intended applications are scientific studies and environmental monitoring which require full time, unattended measurements of the cloud and aerosol height structure. MULTI-ACCESS LASER COMMUNICATIONS TERMINAL Final Report
3 Nov. 1992 305 p Original contains color illustrations
(Contract NAS5-31170; SBIR-14.02-2250)
(NASA-CR-191251; NAS 1.26:191251) Avail: CASI HC A14/MF A03; 3 functional color pages

The Optical Multi-Access (OMA) Terminal is capable of establishing up to six simultaneous high-data-rate communication links between low-Earth-orbit satellites and a host satellite at synchronous orbit with only one 16-inch-diameter antenna on the synchronous satellite. The advantage over equivalent RF systems in space weight, power, and swept volume is great when applied to NASA satellite communications networks. A photograph of the 3-channel prototype constructed under the present contract to demonstrate the feasibility of the concept is presented. The telescope has a 10-inch clear aperture and a 22 deg full field of view. It consists of 4 refractive elements to achieve a telecentric focus, i.e., the focused beam is normal to the focal plane at all field angles. This feature permits image pick-up optics in the focal plane to track satellite images without tilting their optic axes to accommodate field angle. The geometry of the imager-pick-up concept and the coordinate system of the swinging arm and disk mechanism for image pick-up are shown. Optics in the arm relay the telescope focus to a communications and tracking receiver and introduce the transmitted beacon beam on a path collinear with the receive path. The electronic circuits for the communications and tracking receivers are contained on the arm and disk assemblies and relay signals to an associated PC-based operator's console for control of the arm and disk motor drive through a flexible cable which permits +/- 240 deg travel for each arm and disk assembly. Power supplies and laser transmitters are mounted in the cradle for the telescope. A single-mode fiber in the cable is used to carry the laser transmitter signal to the arm optics. The promise of the optical multi-access terminal towards which the prototype effort worked is shown. The emphasis in the prototype development was the demonstration of the unique aspect of the concept, and where possible, cost avoidance compromises were implemented in areas already proven on other programs. The design details are described in section 2, the prototype test results in section 3, additional development required in section 4, and conclusions in section 5. Author

THE HDTV DIGITAL AUDIO MATRIX
A. J. Mason 1993 12 p
(BBC-RD-1993/9) Copyright Avail: Issuing Activity

Multichannel sound systems are being studied as part of the Eureka 95 and Radio-communication Bureau TG10-1 investigations into high definition television. One emerging sound system has five channels; three at the front and two at the back. This raises some compatibility issues. The listener might have only, say, two loudspeakers or the material to be broadcast may have fewer than five channels. The problem is how best to produce a set of signals to be broadcast, which is suitable for all listeners, from those that are available. To investigate this area, a device has been designed and built which has six input channels and six output channels. Each output signal is a linear combination of the input signals. The inputs and outputs are in AES/EBU digital audio format using BBC-designed AESIC chips. The matrix operation, to produce the six outputs from the six inputs, is performed by a Motorola DSP56001. The user interface and 'housekeeping' is managed by a T222 transputer. The operator of the matrix uses a VDU to enter sets of coefficients and a rotary switch to select which set to use. A set of analog controls is also available and is used to control operations other than the simple compatibility matrixing. The matrix has been very useful for simple tasks: mixing a stereo signal into mono, creating a stereo signal from a mono signal, applying a fixed gain or attenuation to a signal, exchanging the A and B channels of an AES/EBU bitstream, and so on. These are readily achieved using simple sets of coefficients. Additions to the user interface software have led to several more sophisticated applications which still consist of a matrix operation. Different multichannel panning laws have been evaluated. The analog controls adjust the panning; the audio signals are processed digitally using a matrix operation. A digital SoundField microphone decoder has also been implemented. The signal processing is a matrix operation, the analog controls being used to adjust the characteristics of the decoded microphone. DSP software for specific tasks not requiring operator control has also been used. Adaptive filtering and signal restoration are two examples. The transputer in this case can be left to perform the housekeeping. The design of the HDTV digital audio matrix is such that it can be applied to a wide variety of signal processing tasks. The combination of a dedicated DSP chip programmed in assembly language for speed of operation and a general purpose processor for user interface tasks programmed in a high level language has been found to be extremely useful. AN INTRODUCTION TO DIGITAL MODULATION AND OFDM TECHNIQUES
M. C. D. Maddocks 1993 13 p
(BBC-RD-1993/10) Copyright Avail: Issuing Activity

This report differs from most BBC Research Department reports in that it does not contain details of a specific project undertaken at Kingswood Warren. While there has been a continuing development of aspects of digital modulation systems by BBC research engineers over many years, the purpose of this report is to be tutorial. That is, digital transmission techniques need to be explained in a general way if full advantage is to be obtained from other reports concerning digital broadcasting transmission systems. There are, however, references to other specialized publications if particular details are required. The text of this report is based on a paper which was prepared for an Institution of Electrical Engineers' vacation school on new broadcast standards and systems. It discusses, at a general level, the various issues and trade-offs that must be considered in the design of a digital modulation system for broadcast use. It particularly concentrates on giving a simple description of the use and benefits of OFDM systems. The particular issues can be applied to various future broadcast systems which are under development at the BBC and as part of collaborative work in international projects. Author (revised)

INTEGRATION AND TEST OF HIGH-SPEED TRANSMITTER ELECTRONICS FOR FREE-SPACE LASER COMMUNICATIONS
Nitin J. Soni and Paul J. Lizanich (Analex Corp., Brook Park, OH.) Feb. 1994 15 p Prepared for presentation at the 15th International Communications Satellite Systems Conference, San Diego, CA, 28 Feb. - 3 Mar. 1994; sponsored by AIAA
(RTOP 506-72-21)
(NASA-TM-106295; E-8033; NAS 1.15:106295; AIAA Paper 94-1158)
Avail: CASI HC A03/MF A01

The NASA Lewis Research Center in Cleveland, Ohio, has developed the electronics for a free-space, direct-detection laser communications system demonstration. Under the High-Speed Laser Integrated Terminal Electronics (Hi-LITE) Project, NASA Lewis has built a prototype full-duplex, dual-channel electronics transmitter and receiver operating at 325 megabit

S per second (Mbps) per channel and using quaternary pulse-position modulation (QPPM). This paper describes the integration and testing of the transmitter portion for future application in free-space, direct-detection laser communications. A companion paper reviews the receiver portion of the prototype electronics. Minor modifications to the transmitter were made since the initial report on the entire system, and this paper addresses them. The digital electronics are implemented in gallium arsenide integrated circuits mounted on prototype boards. The fabrication and implementation issues related to these high-speed devices are discussed. The transmitter's test results are documented, and its functionality is verified by exercising all modes of operation. Various testing issues pertaining to high-speed circuits are addressed. A description of the transmitter electronics packaging concludes the paper. Author (revised)

A LOW NOISE 665 GHz SIS QUASI-PARTICLE WAVEGUIDE RECEIVER

J. W. Kooi, C. K. Walker (Arizona Univ., Tucson.), H. G. LeDuc (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), T. R. Hunter, D. J. Benford, and T. G. Phillips [1993] 16 p

(Grants NAGw-107; NSF AST-90-15755)

(NASA-CR-194735; NAS 1.26:194735) Avail: CASI HC A03/MF A01

Recent results on a 565-690 GHz SIS heterodyne receiver employing a 0.36 micron(sup 2) Nb/AlOx/Nb SIS tunnel junction with high quality circular non-contacting back short and E-plane tuners in a full height wave guide mount are reported. No resonant tuning structures were incorporated in the junction design at this time, even though such structures are expected to help the performance of the receiver. The receiver operates to at least the gap frequency of Niobium, approximately 680 GHz. Typical receiver noise temperatures from 565-690 GHz range from 160K to 230K with a best value of 185K DSB at 648 GHz. With the mixer cooled from 4.3K to 2K the measured receiver noise temperatures decreased by approximately 15 percent, giving roughly 180K DSB from 660 to 680 GHz. The receiver has a full 1 GHz IF pass band and was successfully installed at the Caltech Submillimeter Observatory in Hawaii. Author (revised)

AUTOMATIC MODULATION RECOGNITION BASED ON SPATIAL PATTERN CLASSIFICATION USING ARTIFICIAL NEURAL NETWORKS Final Report

Nasir Ghani Jul. 1992 195 p

(CTN-94-60897) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

In an electronic countermeasures project, an automatic modulation recognition system has been designed and tested based on backpropagation neural networks. The system successfully distinguishes between the specified 10 signal classes to a very high degree and uses a Welch periodogram processor. Experimental results show that the neural networks match and even outdo the performance of the conventional K-nearest neighbor classifier for the same preprocessor, upper 90's percentages. Significant optimization of the neural networks is also shown using the optimal brain damage pruning algorithm. The design issues, preprocessing techniques, backpropagation algorithms, implementation details, and results of the project are fully discussed. A user manual of the software developed during the project, complete with program listings in the C language, is included. Author (CISTI)

CF-18 AN/ALQ-126B-MG 13 IIP INTERFACE TO THE DREO ELECTRONIC WARFARE ENGAGEMENT SIMULATION FACILITY

James Loo and Serge Labeaume Nov. 1992 25 p

(DREO-TN-93-4; CTN-94-60914) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

The AN/ALQ-126B is the radar jammer carried aboard CF-18 fighter aircraft to jam non-coherent pulsed radars. The jammer is software programmable and capable of generating a variety of radar countermeasures signals. To evaluate the effectiveness of radar jammers and jamming techniques, the Defence Research Establishment Ottawa has developed the Electronic Warfare Engagement Simulation Facility (EWESF). The fundamental concepts of electronic countermeasures effectiveness evaluation are described along with the EWESF layout, the AN/ALQ-126B radar jammer, and the jammer interface to the EWESF to jam the MG-13 IIP air intercept radar. Some of the advantages and drawbacks of the configuration are discussed. The EWESF serves as a test bed for operating the jammer and testing its responses on different types of experimental radars. The test configuration is also useful for the CF-18 Integrated Support Station (ISS) project where open-loop jamming tests using new countermeasures techniques may be performed as they are developed. Some limitations of the present test configuration are discussed as well as several modifications to improve the performance and user friendliness of the EWESF. These options include upgrading the scenario control computers and software, upgrading the tracking radar, and adding a continuous target angle motion capability. Author (CISTI)

DETECTION AND ANALYSIS OF UNBALANCED QPSK IN GAUSSIAN NOISE, VERSION 1.0

J. Bodie 1 May 1992 164 p

(DREO-12-020.1; CTN-94-60896) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

The problem of detecting and analyzing a variety of phase shift keying (PSK) signal formats in the presence of noise is addressed. The signal to noise ratios of the discrete tones appearing at the outputs of second- and fourth-order nonlinearities are derived and are used to determine the measurement bandwidth required to achieve given detection statistics. The processor performance requirements are analyzed for fast Fourier transform-based signal detection. Approaches are proposed for the determination of the modulation characteristics of the input signal from the levels of the discrete tones. The performance of phase locked loop carrier and data clock recovery circuits is also analyzed. Author (CISTI)

CODING FOR FREQUENCY HOPPED SPREAD SPECTRUM SATELLITE COMMUNICATIONS Annual Report, 1 Apr. 1990 - 31 Mar. 1991

Q. Wang, G. Li, I. F. Blake (Waterloo Univ., Ontario.), V. K. Bhargava, Q. Chen, and T. A. Gulliver 31 May 1991 166 p

(ECE-91-1; CTN-94-60903) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

A nonlinear diversity combining scheme using the Viterbi ratio threshold (RT) technique is discussed. Performances of the RT diversity combiner in fast frequency hop spread spectrum systems with M-ary frequency shift keying with and without additive white Gaussian noise (AWGN) are analyzed. Exact bit error probabilities are computed and relationships between system performance and parameters such as RT, diversity order, and thermal noise level are illustrated. Performances under band multitone jamming and partial band noise jamming are compared. Performance of M-ary differential phase shift keying (MDPSK) signalling in the presence of both tone jamming and AWGN is described. Larger signal sets than in a previous report are considered along with skewed differential phases with unequal decision regions. The error performance when a frequency offset exists between a jamming tone and a MDPSK carrier is also considered. Error correlation in DPSK demodulation is examined in terms of its effects on the block and decoded error probabilities, which are derived and computed for AWG and worst-case partial band noise. Comparisons are made with the approximate block and decoded error probabilities based on a memoryless model which ignores the error correlation. The effectiveness of interleaving in improving the error performance under various conditions is addressed. Author (CISTI)

ASPT SOFTWARE SOURCE CODE: ASPT SIGNAL EXCISION SOFTWARE PACKAGE

Hugh Parliament 17 Aug. 1992 207 p

(CTN-94-60904) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

The source code for the ASPT Signal Excision Software Package which is part of the Adaptive Signal Processing Testbed (ASPT) is presented. The source code covers the programs 'excision', 'ab.out', 'd0.out', 'bd1.out', 'develop', 'despread', 'sorting', and 'convert'. These programs are concerned with collecting data, filtering out interference from a spread spectrum signal, analyzing the results, and developing and testing new filtering algorithms. A CONSTRAINED OPTIMIZATION TECHNIQUE FOR ARBITRARY ANTENNA ARRAYS AND VARIOUS PERFORMANCE INDICES M.S. Thesis
Li Xiaodan Jun. 1990 112 p
(ISBN-0-315-59455-1; CTN-94-60876) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Some optimization techniques used for optimization of array antenna performance indices are reviewed and evaluated. A new constrained optimization algorithm is presented which uses the Lagrange multiplier and the property of the Hermitian matrix to obtain the optimum solution for the minimum average sidelobe problem in the radiation pattern for arbitrarily configured antenna arrays with constrained conditions, such as steerable pencil beam, multi-beam, and null steering. The algorithm is presented for different array configurations and element patterns, with emphasis on the microstrip circular patch antenna array. The modelling of mutual coupling between microstrip elements is also discussed. The utilization of Bessel functions and the symmetry property of Hermitian matrices are presented in this algorithm, which greatly improves the computational efficiency. Another important complement is to include other array performance indices into the objectives of the algorithm, such as radiation efficiency. The developed algorithm is useful for optimized antenna array design and provides an approach to test and simulate radiation performance for arrays of different configuration and element type. Numerical results are illustrated in the form of printed tables or two- and three-dimensional plots. Author (CISTI)

A satellite communication system is disclosed which provides an increased probability of reception by selective call receivers. In carrying out the invention in one form, there is provided a method comprising the step of relaying, from two or more locations via at least one satellite, a transmission to a receiver. By relaying the information being transmitted from two different locations (angles) at different points in time, the probability of reception is increased. Programming means are provided for determining the first and second locations and times of transmitting the information. Author (CISTI)

EVALUATION OF EHF MULTI-BEAM ADAPTIVE ARRAYS Final Report
J. L. Yen and P. Kremer 30 Apr. 1992 27 p
(CTN-94-60898) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

An experimental three-beam 44-GHz adaptive antenna for frequency hopped communication systems is described. A software package called AJSIM for the simulation of multi-beam antennas and multi-element arrays for anti-jamming in frequency hopping systems is presented. The software makes use of a graphics user interface and allows visualization of many pertinent operational performances of the array under simulation. The simplifying assumptions, the method of analysis, and some results and deductions are included. The evaluation of the experimental three-beam anti-jamming antenna confirms that such an array performs as predicted. Optimization of element weights in such a small array can be achieved without a sophisticated controller. Simulation studies using AJSIM indicate that arrays are superior to a single multi-beam antenna for anti-jamming because of the grating lobes and the ability to produce deep holes in the pattern. AJSIM can be used to perform a systematic search for user-jammer scenarios which are vulnerable to a particular array-beam configuration. A user manual for AJSIM is appended. Author (CISTI)

PROPWR: A VERSATILE TOOL FOR 1/3 OCTAVE PROCESSING AND NARROWBAND LINE TRACKING
Joseph B. Farrell Feb. 1993 47 p
(DREA-TC-93-303; CTN-94-60911) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

PROPWR is a versatile power spectrum processing program designed to process both real and complex format power spectrum files. The program runs on Concurrent Computer Corporation 5000-6000 series and Digital Equipment VAX computers. PROPWR has a powerful user interface which allows wide latitude in setting up parameters for calibration of power spectra, 1/3 octave calculations, and narrowband line tracking. Some of the main features of the program include: 1/3 octave processing of Defense Research Establishment Atlantic format power spectrum files, with selectable parameters including frames and channels to process, center frequency of first 1/3 octave band, and output file format; time series of power levels in 1/3 octave bands; fully configurable tracking (frequency, signal level, and noise level) of up to 20 narrowband lines; and calibration of power spectrum data. A sample terminal session is included along with a description of the user interface. Author (CISTI)

A SIMULATION AND EVALUATION OF NATO STANDARDIZATION AGREEMENT (STANAG) 4214 M.S. Thesis
Michael A. Dorko and Robert G. Schultz Sep. 1993 124 p
(AD-A273195) Avail: CASI HC A06/MF A02

An object-oriented simulation model is developed to evaluate the effectiveness of NATO Standardization Agreement (STANAG) 4214, which promulgates the protocol for international telephone call routing and directories for tactical communications. The model simulates communication systems using the STANAG 4214 protocol to isolate discrepancies which could lead to the inability to successfully complete calls within the system. The model also simulates protocol modifications created to correct existing discrepancies and verifies their effectiveness in making the protocol more robust. Results show that these modifications improve STANAG call completion rate from a potential low of under 70 percent to 100 percent, while simultaneously easing the restrictions on lateral communication connections. The model is menu-driven with both graphical and hard copy output, making it useful to network planners, protocol designers, and tactical communications officers. DTIC

In the fall of 1992, the design and analysis of a lunar-based optical interferometer telescope array was initiated by a group of students in the Department of Aerospace Engineering at Virginia Tech. This project was undertaken at the suggestion of the Space Exploration Initiative Office at the NASA Langley Research Center. The original array design requirements, listed below, centered on the primary objective of resolving earth-type planets about stars out to a distance of ten parsecs: spectrum coverage spanning wavelengths from five nm to five mm, with a primary operating mode in the visible spectrum; a total collecting area providing a signal-to-noise ratio (SNR) of no less than 10.0 for a median wavelength of 500 nm; the individual array elements must be identical and have a maximum optical diameter of 2.0 m; and lunar site selection is limited to ten degrees north and south of the lunar equator on the lunar far side while not closer than 15 degrees to either near-side limb. Following construction by astronaut crews, array operation will be conducted from earth and astronomical observations will not be conducted during the lunar day. The entire system is designed for minimum achievable mass. The majority of the original design requirements for the telescope array were met. Derived from text

In finite element methods for solving electromagnetic field problems, the use of edge elements has become very popular. In fact, edge elements are often believed to be a cure for many difficulties that are encountered, and they are claimed to yield accurate results. In the present paper, we shall analyze these claims for tetrahedral elements. In particular, we shall compare two different types of 'linear' edge elements and the classical linear nodal element, comparisons for higher order elements and elements defined on other shapes, for instance on cubes, run along the same lines and yield similar conclusions. An efficient and accurate finite-element method is presented for computing transient as well as time-harmonic electromagnetic fields in three-dimensional configurations containing arbitrarily inhomogeneous media that may be anisotropic. To obtain accurate results with an optimum computational efficiency, both consistently linear edge and consistently linear nodal elements are used for approximating the spatial distribution of the field. As compared with earlier work, our formulation is generalized by adding a method for explicitly modeling the normal continuity along interfaces that are free of surface charge. In addition to this, the conditions for efficiently solving time-harmonic problems using a code designed for solving transient problems are discussed. Finally, a general and simple method for implementing arbitrary inhomogeneous absorbing boundary conditions for modeling arbitrary incident fields is introduced. NTIS

Formulations for scattering from the coated plate and the coated dihedral corner reflector are included. A coated plate model based upon the Uniform Theory of Diffraction (UTD) for impedance wedges was presented in the last report. In order to resolve inaccuracies and discontinuities in the predicted patterns using the UTD-based model, an improved model that uses more accurate diffraction coefficients is presented. A Physical Optics (PO) model for the coated dihedral corner reflector is presented as an intermediary step in developing a high-frequency model for this structure. The PO model is based upon the reflection coefficients for a metal-backed lossy material. Preliminary PO results for the dihedral corner reflector suggest that, in addition to being much faster computationally, this model may be more accurate than existing moment method (MM) models. An improved Physical Optics (PO)/Equivalent Currents model for modeling the Radar Cross Section (RCS) of both square and triangular, perfectly conducting, trihedral corner reflectors is presented. The new model uses the PO approximation at each reflection for the first- and second-order reflection terms. For the third-order reflection terms, a Geometrical Optics (GO) approximation is used for the first reflection; and PO approximations are used for the remaining reflections. The previously reported model used GO for all reflections except the terminating reflection. Using PO for most of the reflections results in a computationally slower model because many integrations must be performed numerically, but the advantage is that the predicted RCS using the new model is much more accurate. Comparisons between the two PO models, Finite-Difference Time-Domain (FDTD) and experimental data are presented for validation of the new model. Author (revised)

OPTIMIZATION OF TECHNIQUES TO RECONSTRUCT IMAGES DISTURBED BY ATMOSPHERIC TURBULENCE IN THE NEAR INFRA-RED Final Report [OPTIMISATION DE TECHNIQUES DE RECONSTRUCTION D'IMAGES PERTURBEES PAR LA TURBULENCE ATMOSPHERIQUE DANS LE PROCHE INFRA-ROUGE]
P. Ghez 1993 14 p In FRENCH Sponsored by Direction des Recherches, Etudes et Techniques Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-199784) Avail: Issuing Activity (National Technical Information Service (NTIS))

The author optimized an instrument for reconstructing images at the diffraction limit. The work involved optimizing signal processing for an interferometry experiment in the aperture diaphragm plane, establishing processing and image-correction algorithms, and reconstructing images from two-dimensional astronomical sources using interferometric data. The main advantage of the device is that it provides a self-calibrated measurement of the visibility module. Measurements are independent of atmospheric turbulence provided that turbulence is correctly established and sampled. The major drawback is that it does not provide an image directly, supplying only its Fourier transform. NTIS

FINITE-ELEMENT METHOD FOR COMPUTING THREE-DIMENSIONAL ELECTROMAGNETIC FIELDS IN INHOMOGENEOUS MEDIA (1993)
Gerrit Mur and Ioan Lager (Transilvania Univ., Brasov, Romania.) 1993 14 p See also PB86-147022 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-111101; ET/EM-1993-13) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

An efficient and accurate finite-element method is described for computing three-dimensional time-harmonic electromagnetic fields in strongly inhomogeneous, (an)isotropic media, such as are encountered in the human body, subsurface structures of the earth, and in many engineering applications. For the expansion of the field in an inhomogeneous configuration, Cartesian (nodal) elements are used in its homogeneous subdomains and edge elements are used to account for the continuity relations of the field across the interfaces between those subdomains. In the domain of computation the FEMAX package in which this approach has been implemented decides locally what type of element has to be used for obtaining the user-specified accuracy of modeling the field. In this way, optimum results are obtained both in regard to computational efficiency and in regard to desired accuracy. The electromagnetic compatibility relations are used for elimination of spurious solutions. Numerical results are presented that demonstrate the package to be efficient as well as accurate. NTIS

SERVICE DESCRIPTION OF COMMUNICATION SYSTEMS SUPPORTING MULTI-MEDIA MULTI-USER APPLICATIONS

G. J. Heijenk, X. Hou, and I. G. Niemegeers 1993 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-110855; TIOS-93/20) Copyright Avail: CASI HC A03

The paper presents a service description of communication systems supporting multi-media multi-user applications. In particular, it focuses on service elements related to the call control. The service description specifies the functional behavior of the communication system as a whole. It can be used as a common reference in the next design stages, e.g., in the protocol design and implementation of both Customer Premises Networks and public telecommunication networks. After discussing the requirements of multi-media multi-user applications, a call model is presented. This model creates an abstract view of those aspects of the call relevant for the design and helps us in structuring the service. Only those service elements of a communication system that are related to the call establishment, modification and termination are fully specified by describing service primitives, their parameters and temporal ordering constraints. THE USE OF HARMONICS IN 3-D MAGNETIC FIELDS

S. Caspi, M. Helm, and L. J. Laslett Sep. 1993 4 p Presented at the 13th International Conference on Magnet Technology, Victoria, Canada, 20-24 Sep. 1993

(Contract DE-AC03-76SF-00098)

(DE94-002274; LBL-33432; CONF-930926-18) Avail: CASI HC A01/MF A01

Motivated by the need for new means for specification and determination of 3-D fields that are produced by electromagnetic lens elements in the region interior to coil windings and seeking to obtain techniques that will be convenient for accurate conductor placement and dynamical study of particle motion, the authors have generalized the representation of a 2-D magnetic field to 3-D. They have shown that the 3-D magnetic field components of a multipole magnet in the curl-free divergence-free region near the axis $r = 0$ can be derived from one dimensional functions A(sub n)(z) and their derivatives. In this report they apply both methods to the 'end' region of a 40 mm bore SSC quadrupole, calculating first the field harmonics and then reconstructing the field comparing both results with direct Biot-Savart calculation. COMPARISON OF HF GROUNDWAVE PROPAGATION MODELS M.S. Thesis

Celso V. Davila Jun. 1993 70 p

(AD-A273146) Avail: CASI HC A04/MF A01

The groundwave component of high frequency (HF) radio propagation is utilized in both civilian and military applications. A variety of groundwave propagation models exist to predict field strength loss over the transmission path. In this thesis, groundwave field strength predictions were compared for programs which employ such models: GRWAVE, MIXPATH, and ADVANCED PROPHET. A range of parameter values was used to generate predictions for comparison. HF groundwave field strength predictions by PROPHET were 3 to 10 dB stronger than those of the other programs. GRWAVE and MIXPATH field strength predictions were in close agreement, the difference generally being less than 1 or 2 dB. Field measurements of path loss for two AM broadcast frequencies were evaluated by comparison with estimates provided by ADVANCED PROPHET. The measured groundwave field strengths were found to be from 8 dB weaker at short distances to 18 dB stronger at large distances it is recommended that future efforts be directed toward improving and validating the accuracy of the groundwave propagation models used in these programs. It is also recommended that more extensive documentation be developed for GRWAVE. DTIC

SIMULATION OF ADJACENT CHANNEL INTERFERENCE IN A UHF SATELLITE SYSTEM M.S. Thesis

Juan C. Minuto Sep. 1993 71 p

(AD-A273147) Avail: CASI HC A04/MF A01

In this thesis, the adjacent channel interference in a ultra high frequency (UHF) satellite channel is evaluated by simulation differential binary phase-shift keying (DBPSK) and is compared with continuous phase frequency-shift keying (CPFSK). First, a measure of the interfering power is obtained and a method to compute carrier-to-interference ratios in a non-linear channel is developed. Next a DBPSK receiver is simulated when two interfering channels separated in frequency are present, and bit errors are detected and counted. Then, coherent reception of minimum-shift keying (MSK) and CPFSK with modulation index $h = 0.4$ are simulated in the same conditions as DBPSK. Finally, noncoherent MSK is analyzed in the same way, and a comparative behavior it obtained. It is found that the best performance in the presence of adjacent channel interference is given by coherent reception of MSK. DTIC

MITIGATION OF EMI/RFI PRODUCED BY A 1.2 kW UNINTERRUPTIBLE POWER SUPPLY M.S. Thesis

Efthimios Mikros Sep. 1993 129 p

(AD-A273149) Avail: CASI HC A07/MF A02

Recently installed equipment in naval receiving sites, such as Uninterruptible Power Supplies (UPS), digital telephone switching systems, and personal computers, inject noise into receiver systems via power conductors, cable shields, and grounds, thus reducing the probability of intercept of a signal of interest in the 2-100 NMHz range. In this thesis a survey of EMI/RFI sources at receiving sites is performed. The effectiveness of a Barrier-Filter-Ground architecture in containing/eliminating EMI/RFI from a 1.2 kW UPS is tested. The spectral and temporal properties of the EMI/RFI from the UPS are recorded. Estimates for the EMI/RFI power are obtained from 60Hz to 100kHz, and a possible solution is proposed for obtaining noise power estimates for higher frequencies. DTIC

ELF COMMUNICATIONS SYSTEM ECOLOGICAL MONITORING PROGRAM Summary Report, 1982-1992

J. E. Zapotosky and J. R. Gauger Oct. 1993 107 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00039-93-C-0001)

(AD-A273456; IITRI-D06205-3) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The U.S. Navy has been conducting a long-term monitoring program to examine flora, fauna, and their ecological relationships for possible effects from electromagnetic fields produced by its Extremely Low Frequency (ELF) Communications System. Physiological, developmental, behavioral, and ecological variables for dominant biota in upland, wetland, and riverine habitats near the ELF System have been examined since 1982. Monitoring studies use a split-plot or blocked design to examine differences in space and time. Observations have been made during preoperational, intermittent-use, and full-operational use periods near ELF transmitters located-in Michigan and Wisconsin. Data collection for studies located near the Naval Radio Transmitting Facility (NRTF)-Clam Lake, Wisconsin, was completed, as scheduled, during 1989. Investigators concluded that there were no effects from intermittent or full operations of the transmitter in Wisconsin. Data collection for studies located near the NRTF-Republic, Michigan, progressed during 1992 and are to continue during 1993. Final results and conclusions for Michigan studies are expected after all data have been analyzed in 1994. DTIC

INTEGRATED REFLECTOR ANTENNA DESIGN AND ANALYSIS Final Report
M. L. Zimmerman, S. W. Lee, S. Ni, M. Christensen, and Y. M. Wang Oct. 1993 188 p
(Contract NCC3-156)
(NASA-CR-195164; NAS 1.26:195164; TR-94-4) Avail: CASI HC A09/MF A02

Reflector antenna design is a mature field and most aspects were studied. However, of that most previous work is distinguished by the fact that it is narrow in scope, analyzing only a particular problem under certain conditions. Methods of analysis of this type are not useful for working on real-life problems since they can not handle the many and various types of perturbations of basic antenna design. The idea of an integrated design and analysis is proposed. By broadening the scope of the analysis, it becomes possible to deal with the intricacies attendant with modem reflector antenna design problems. The concept of integrated reflector antenna design is put forward. A number of electromagnetic problems related to reflector antenna design are investigated. Some of these show how tools for reflector antenna design are created. In particular, a method for estimating spillover loss for open-ended waveguide feeds is examined. The problem of calculating and optimizing beam efficiency (an important figure of merit in radiometry applications) is also solved. Other chapters deal with applications of this general analysis. The wide angle scan abilities of reflector antennas is examined and a design is proposed for the ATDRSS triband reflector antenna. The development of a general phased-array pattern computation program is discussed and how the concept of integrated design can be extended to other types of antennas is shown. The conclusions are contained in the final chapter. Author (revised)

ANALOG COMMUNICATION TRANSMITTER AND RECEIVER TEST PROCEDURES Final Report
13 Oct. 1993 105 p
(AD-A273423; ITOP-6-2-242) Avail: CASI HC A06/MF A02

This ITOP defines and describes the necessary test procedures to be conducted for evaluating the performance of analog modulated (AM and FM) communication transmitters and receivers. Although this document provides a full test suite, the amount of testing conducted for a specific test item should be in accordance with its anticipated conditions of use and quality level. In order to provide a broad scope of application, this document does not impose any specification limits. Therefore, those limits may be derived from the equipment specifications or any established sources such as MIL-STD's or other national and European standards. Some test parameters are specified, however, to produce test data allowing performance comparisons between different equipment. The scope of these procedures is comprehensive enough to model complete systems (made of several transmitters and receivers) and to derive system performance or inter-system compatibility data. DTIC

ANALYSIS OF TIME-DIVERSITY COMBINING METHODS FOR FREQUENCY-HOPPED SIGNALS
Rolands Ezers and J. S. Wight Apr. 1992 71 p
(CU-DOE-92-09; CTN-94-60899) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

Fast frequency hopped (FFH) noncoherent frequency shift keyed (NCFSK) communication systems with time diversity (TD) and diversity combining are discussed. A literature review of diversity combining techniques is provided. An analytical method was developed for one of the techniques, linear diversity combining (LDC). With this method, the bit error probability for demodulation of FFH NCFSK systems with TD and LDC and the probability of detection and probability of false alarm for uplink coarse-time synchronization of a FFH NCFSK satellite communication system with TD and LDC combining have been computed in broadband noise and multiple-tone jamming. A novel analytical result was derived for computing the bit error probability for the demodulation of FFH NCFSK systems with TD and 4-2- or 2-1-moment method diversity combining in independent Rayleigh fading. For demodulation, LDC is an excellent method in broadband noise and good in severe multiple tone jamming. In weak multiple tone jamming, LDC is not a good method because of its susceptibility to Houston-sense multiple tone jamming with a small jamming fraction. In independent Rayleigh fading, square-law combining was best for the particular situation considered. TD and LDC could be used to improve performance in uplink coarse-time synchronization. The composite sequences, a class of spreading sequences for direct-sequence spread spectrum communication (DS-SS), is investigated for the case of components which are binary maximal length sequences. The relevant properties of the composite sequences are derived and the acquisition time performance is determined for a noisy environment. It is demonstrated that the composite sequences are a large, balanced class of spreading sequences with a high linear span, reasonable autocorrelation performance, an essentially featureless power spectrum, improved security, and rapid acquisition capability. A novel subclass of composite sequences, termed the sliding composite sequences (SCS), is also presented, and their properties and performance are investigated and derived. It is shown that SCS are a large, nearly balanced class of spreading sequences with high linear span, an essentially featureless power spectrum, and improved security. Most importantly, through exploitation of the inherent rapid acquisition structure of SCS construction, a novel acquisition algorithm is developed which gives orders of magnitude reduction in acquisition time for DS-SS communications. In addition, a novel algorithm for generating primitive polynomials is presented and the aperiodic autocorrelation magnitude of m-sequences is bounded empirically. Author (CISTI)

The performance of fast frequency hopped spread spectrum systems with M-ary frequency shift keying and error correction coding under jamming conditions are analyzed. Ratio threshold diversity combining is used. The decoding scheme is error erasure decoding with metrics generated by the diversity combiner. The bit error probability of the system is computed and improvements offered by error correction coding are shown. The performance of several error correction codes is compared under different channel conditions. The notion of an arbitrarily varying channel (AVC) is discussed, including capacities of AVC's and a discrete memoryless channel, and two Gaussian AVC models are described. Coded performance of a slow frequency hopped differential phase shift keying (DPSK) system in presence of both additive white Gaussian noise and tone jamming is studied. The error correlation due to DPSK demodulation and the effect of tone jamming are considered in evaluating the block and decoded error probabilities. The effect of interleaving on system performance is addressed. A nearly optimum code rate for a length 255 Reed-Solomon code is derived for systems employing interleaving. Finally, a parallel approach to the design of universal receivers for unknown and time-varying channels is applied to DPSK systems in the presence of noise and tone interference.

The emergence of broadband ISDN as the network for the future brings with it the promise of integration of all proposed services in a flexible environment. In order to achieve this flexibility, asynchronous transfer mode (ATM) has been proposed as the transfer technique. During this period a study was conducted on the bridging of network transmission performance and video coding. The successful transmission of variable bit rate video over ATM networks relies on the interaction between the video coding algorithm and the ATM networks. Two aspects of networks that determine the efficiency of video transmission are the resource allocation algorithm and the congestion control algorithm. These are explained in this report. Vector quantization (VQ) is one of the more popular compression techniques to appear in the last twenty years. Numerous compression techniques, which incorporate VQ, have been proposed. While the LBG VQ provides excellent compression, there are also several drawbacks to the use of the LBG quantizers including search complexity and memory requirements, and a mismatch between the codebook and the inputs. The latter mainly stems from the fact that the VQ is generally designed for a specific rate and a specific class of inputs. In this work, an adaptive technique is proposed for vector quantization of images and video sequences. This technique is an extension of the recursively indexed scalar quantization (RISQ) algorithm. FEASIBILITY STUDY OF A SYNTHESIS PROCEDURE FOR ARRAY FEEDS TO IMPROVE RADIATION PERFORMANCE OF LARGE DISTORTED REFLECTOR ANTENNAS Final Report
W. L. Stutzman, K. Takamizawa, and J. LaPean Dec. 1993 17 p
(Grant NAG1-859)
(NASA-CR-195167; NAS 1.26:195167; SATCOM-93-20) Avail: CASI HC A03/MF A01

There were several tangible products that resulted from the reflector antenna research program. The initial technical effort was to develop techniques to compensate for distortions over the surface of the main reflector of a large reflector antenna system. An in-depth investigation of this problem resulted in a new technique for the electronic correction of surface errors. A journal article on the findings describe the use of the iterative sampling method. Shortly after the 'Mission to Planet Earth' program started, we began investigating the use of large reflector antennas in geostationary orbit for passive earth remote sensing. A study panel was coordinated by Virginia Tech to set technical goals for the effort. These were used to guide the design of several antennas. The original interest stemmed from an industrial (Reynolds Metals) need and currently involves work with industry (Prodelin Corporation) on high technology, low cost reflectors. The intervening years (1987 - 1993) is the period of this report and Virginia Tech's reflector antenna activity then was exclusively with NASA LaRC. Derived from text

CONVEYING DIGITAL DATA IN NOISY, UNSTABLE, MULTIPATH ENVIRONMENTS Patent
Richard A. Daniel, inventor (to Navy) 24 Aug. 1993 12 p Filed 24 Jun. 1991
(AD-D015980; US-Patent-5,239,560; US-Patent-Appl-SN-720129; US-Patent-Class-375-38) Avail: US Patent and Trademark Office

This patent discloses a decoding system for transmitting a signal through a noisy, unstable multipath environment. In this system, the signal consisting of eight possible symbols is encoded using four of eight possible frequencies in an orthogonal Hadamard matrix, transmitted through the environment, and decoded using the same orthogonal Hadamard matrix. This provides a correlation result which can compensate for at least one error in the received signal for each symbol. DTIC

RADAR TARGET DISCRIMINATION BY SPECTRUM ANALYSIS Patent
Duane Ruth, inventor (to Navy) and Larry M. Morrison, inventor (to Navy) 3 Aug. 1993 24 p Filed 13 Nov. 1992
(AD-D015982; US-Patent-5,233,354; US-Patent-Appl-SN-976048; US-Patent-Class-342-160) Avail: US Patent and Trademark Office

A method for distinguishing between a target and clutter analyzes frequency components of returned wave energy to detect target energy characterized by being present in a narrow range of frequencies, by increasing in the range over time, or by remaining substantially in the range over time. The method utilizes time sequential spectra of the returned energy. The spectra may be signals from a plurality of band pass filters or may be a spectrogram. The energy in adjacent band pass signals and spectra frequencies are correlated to detect energy in a narrow range of frequencies. Differences in successive spectra are integrated to detect increasing energy in a range of frequencies. An energy peak detected in a narrow range by correlation is integrated to detect that the peak remains in the range. The method is adapted for use with a network having inputs receiving successive samples of the returned energy and having outputs individually connected to the inputs through multiplier elements providing selectable factors, a summing element, and a selectable and generally sigmoidal activation function. RADAR TARGET DISCRIMINATION SYSTEMS USING ARTIFICIAL NEURAL NETWORK TOPOLOGY Patent
Larry M. Morrison, inventor (to Navy) and Duane Roth, inventor (to Navy) 10 Aug. 1993 25 p Filed 13 Nov. 1992
(AD-D015984; US-Patent-5,235,339; US-Patent-Appl-SN-977301; US-Patent-Class-342-159) Avail: US Patent and Trademark Office

A system for distinguishing between a target and clutter is presented. The system analyzes the frequency components of returned wave energy by one or more networks each having inputs receiving successive samples of the returned energy and having outputs individually connected to the inputs through multiplier clements providing selectable factors. The multipliers corresponding to each output are connected to the output through a summing element and a selectable and generally sigmoidal activation function. The factors may be bandpass filter coefficients or discrete Fourier transform coefficients so as to generate frequency components of the energy. Predetermined frequency characteristics of the returned energy may be detected by providing the outputs of a network to a network in which the factors are selected as correlation or convolution coefficients, are selected to integrate feedback outputs, or are selected to sum several outputs within a predetermined range. The activation functions may be selected for thresholding, linearity, limiting, or generation of logarithms. DTIC

LAYERED PARALLEL INTERFACE FOR AN ACTIVE ANTENNA ARRAY Patent
William M. Waters, inventor (to Navy) 21 Sep. 1993 13 p Filed 24 Jun. 1992
(AD-D016002; US-Patent-5,247,310; US-Patent-Appl-SN-903316; US-Patent-Class-342-368) Avail: US Patent and Trademark Office

A transmit/receive layer is provided adjacent to an array of antenna elements. The transmit/receive layer has an array of transmit receive modules, each module associated with one of the antenna elements. An analog to digital converter and a digital to optical converter of one of the modules couple an RF signal from the associated antenna element to optical fibers. An optical to RF converter in each of the modules converts an amplitude modulated optical transmit signal from an optical fiber to an RF transmit signal for transmission by the associated antenna element. Frequency down and up converters can be added to perform super heterodyne frequency conversion based on a reference frequency control signal transmitted over the optical fibers. At the ends of the optical fibers opposite to the transmit/receive layer, a receive layer, a transmit layer, transmit and receive beamforming layers, dedicated signal synthesizer, control signals, and amplitude modulated optical diode lasers and photodiodes are provided. PREPROCESSOR AND ADAPTIVE BEAMFORMER FOR LINEAR-FREQUENCY MODULATION ACTIVE SIGNALS Patent
James C. Lockwood, inventor (to Navy) 5 Oct. 1993 25 p Filed 6 Oct. 1992
(AD-D016008; US-Patent-5,251,186; US-Patent-Appl-SN-957544; US-Patent-Class-367-103) Avail: US Patent and Trademark Office

A device is provided for processing an echo received by an array of N receiving elements from a target at range R ensonified by a linear-frequency modulation (LFM) signal of bandwidth B transmitted for a duration T. The device receives each elements output f(sub n(t)) over the elements total receiving time and selects time window element outputs f(sub n(t)), which are discrete portions of f(sub n(t)), each time window extending from an arbitrary initial time T(sub o) to time T(sub f) and is spaced from. T(sub o) no more than T and, if there is a target within the window, an echo is received at time T(sub n). Further the device produces element frequency difference outputs g(sub n(t)) from the frequency difference between a replica of at least a portion of the transmitted LFM signal and the time window, element outputs f(sub n(t)), the outputs g(sub n(t)) being tones with frequencies directly proportional to the time T(sub n) of the target from the time To so that the target range R=(c/2)(T(sub o) + T(sub n)) + delta(R(sub n)), where cis the speed of sound, and delta R, is the distance by which R exceeds each element's range to the target. VERY LOW FREQUENCY AND LOW FREQUENCY TRANSMITTING ANTENNA PARAMETER MONITORING SYSTEM Patent
Steven C. Tietsworth, inventor (to Navy) 3 Aug. 1993 40 p Filed 11 Jun. 1991
(AD-D015989; US-Patent-5,233,537; US-Patent-Appl-SN-713658; US-Patent-Class-364-481) Avail: US Patent and Trademark Office

A very low frequency and low frequency transmitting antenna parameter monitoring system is used to measure the electric circuit parameters in near real time of very low frequency and low frequency transmitting antenna systems transmitting frequency shift keyed modulation. The primary parameters measured by the system are the antenna feed-point voltage, antenna current, gross resistance, gross reactance, and steady-state phase angle between the voltage and current. Four primary sections provide for antenna system sensing by sensors, triggering, analog-to-digital conversion of the sensor outputs, and computer processing of the digital data to arrive at the desired antenna parameters. These parameters are essential in evaluating antenna performance and in diagnosing problems with the antenna system. DTIC

METHOD AND APPARATUS OF GENERATING SUM OR DIFFERENCE SIGNALS CORRESPONDING TO AN APPARENT BEAM IN A MONOPULSE RADAR SYSTEM Patent
Dean D. Howard, inventor (to Navy) 31 Aug. 1993 16 p Filed 29 May 1992
(AD-D015998; US-Patent-5,241,318; US-Patent-Appl-SN-889920; US-Patent-Class-342-149) Avail: US Patent and Trademark Office

The invention relates to an apparatus and method for generating target range, azimuth angle, or elevation angle output signals corresponding to an apparent beam in a multiple-feed monopulse radar system. The multiple-feed monopulse radar system according to the present invention includes a transmitter/receiver unit, an adder/subtracter unit and a video comparator/adder unit. The transmitter/receiver unit is used to generate first and second actual antenna beams. Echoes caused by such actual beams are received and processed to provide first sum and first difference signals and second sum and second difference signals corresponding to the first and second actual beams, respectively. These signals are then supplied to the adder/subtracter unit which adds the first sum and first difference signals to provide a result sigma(sub 1) + K delta(sub 1), subtracts the first sum and first difference signals to provide a result sigma(sub 1) - K delta, adds the second sum and second difference signals to provide a result sigma(sub 2) + K delta (sub 1), and subtracts the second sum and second difference signals to provide a result sigma(sub 2) - K delta(sub 2). SYSTEM FOR PRODUCING SYNCHRONIZED SIGNALS Patent
Louis M. Pecora, inventor (to Navy) 14 Sep. 1993 13 p Filed 19 Feb. 1991
(AD-D016003; US-Patent-Appl-SN-656330; US-Patent-Class-380-48) Avail: US Patent and Trademark Office

A system for producing two synchronized signals comprises a nonlinear dynamical primary system and a nonlinear dynamical secondary response subsystem. The primary system comprises a nonlinear dynamical drive subsystem for producing at least one drive signal, and a nonlinear dynamical primary response subsystem responsive to said at least one drive signal for producing a primary signal, wherein said primary response subsystem has a complete set of at least one primary sub-Lyapunov exponents, all of said at least one primary sub-Lyapunov exponents being negative. The second response subsystem is responsive to said at least one drive signal for producing a secondary signal in synchronization with said primary signal, said secondary response subsystem being substantially a duplicate of said primary response subsystem, wherein said secondary response subsystem has a complete set of at least one secondary sub-Lyapunov exponents, all of said at least one secondary sub-Lyapunov exponents being negative. DTIC

N94-25058 Department of the Navy, Washington, DC.
METHOD AND APPARATUS FOR DETERMINING TARGET ELEVATION ANGLE, ALTITUDE AND RANGE, AND THE LIKE IN A MONOPULSE RADAR SYSTEM WITH REDUCED MULTIPATH ERRORS Patent
Dean D. Howard, inventor (to Navy) 31 Aug. 1993 18 p Filed 29 May 1992
(AD-D016005; US-Patent-5,241,317; US-Patent-Appl-SN-889806; US-Patent-Class-342-149) Avail: US Patent and Trademark Office

The present invention relates to a method and system for determining target elevation angle, altitude, range, and the like in a monopulse radar system with reduced multipath errors. A transmitter/receiver unit receives monopulse sum and difference signals caused by echoes from targets. The sum and difference signals are then logarithmically amplified in a logarithmic amplifier unit. A selector selects one of the sum and difference signals having the largest amplitude, and generates a selection signal indicating which of the sum and difference signals has the largest amplitude. The selection signal is provided to search radar target tracking unit which determines whether a target at a given range interval and azimuth interval, for example, has been selected for tracking by an operator. The search radar target tracking unit then controls a gate unit to selectively provide either the logarithmically amplified sum signal or the logarithmically amplified difference signal to a peak detection unit based on the selection signal, and based on whether a particular target has been selected for tracking. PSYCHOPHYSICAL AND SIGNAL-PROCESSING ASPECTS OF SPEECH REPRESENTATION Ph.D. Thesis
Changxue Ma 1992 140 p
(ETN-94-95292) Avail: CASI HC A07/MF A02

The ways to improve the Linear Prediction Code (LPC) analysis and synthesis techniques are studied. An improved way to estimate the LPC parameters, in particular for high pitched voices and to estimate the time instants of glottal closure, is presented. A new weighted LPC analysis of speech is investigated. In this approach, a weighting function is derived from the short time energy function of the speech signal. The estimates of the LPC coefficients by this novel LPC analysis are therefore more accurate than those obtained from the conventional LPC analysis. The relation between the Covariance Linear Prediction (CLP) analysis of a frame of a speech signal and the CLP analysis of its subframes is established. A Singular Value Decomposition (SVD) approach is developed to detect the glottal closure instant in the speech signal. A new approach for ascertaining whether a signal is uniquely determined by the phase of its Fourier transform is discussed. It is shown that uniqueness corresponds to the nonsingularity of a matrix which can be formed from the finite length real sequence. The perceptual study of speech sounds, mainly concerned with auditory masking, is carried out. ESA

NORTHERN EXPOSURE 1992: AN INVESTIGATION OF TRANSAURORAL HF RADIO SKYWAVE PROPAGATION Interim Report
Leonard S. Wagner, Joseph A. Goldstein, Michael A. Rupar, and Edward J. Kennedy 29 Sep. 1993 52 p
(NR Proj. LR0-330244)
(AD-A273363; NRL/FR/5554-93-9575) Avail: CASI HC A04/MF A01

The primary objective of the Northern Exposure 92 campaign was to assist in the evaluation of the performance capabilities of a wideband, high frequency, Rake radio receiver on a transauroral skywave channel. A review of the data collected on the transauroral channel during the Northern Exposure 92 exercises indicates that one is likely to encounter three types of signals on the channel: (1) a strong, specularly reflected signal characterized by the usual ionospheric dispersive delay spread and negligible Doppler spread, (2) strong specular multipath signals, exhibiting extensive delay and Doppler spread, and (3) weak scatter signals, exhibiting the widest delay and Doppler spreads. The nonspread reflected signals are encountered during magnetically quiet, daytime conditions where the ionosphere may be described as laminar. The strong, specular-multipath signals occur mostly at night and are associated with reflections from large scale irregularities of electron density characterized by strong horizontal gradients capable of reflecting signals whose frequencies lie below some equivalent maximum usable frequency (MUF) defined by the path, the background ionosphere, and the maximum electron density in the irregularity region. The weak scattered signals occur at night and are associated with volume scatter from the irregular medium. The scattered signals present the greatest challenge to communication systems with amplitudes approx. 30 dB less than those of reflected signals and with 2 sigma Doppler spreads as large as 30 Hz. (NASA-CR-195131; NAS 1.26:195131) Avail: CASI HC A03/MF A01

The Community College Division is pleased to report progress of NASA funded research at West Virginia State College. During this reporting period, the project research group has continued with activities to develop instrumentation capability designed to monitor resonant cavity frequencies in the atmospheric region between the Earth's surface and the ionosphere. In addition, the project's principal investigator, Dr. Craig Spaniol, and NASA technical officer, Dr. John Sutton, have written and published technical papers intended to expand the scientific and technical framework needed for project research. This research continues to provide an excellent example of government and education working together to provide significant research in the college environment. This cooperative effort has provided many students with technical project work which compliments their education. For individual titles, see N94-25192 through N94-25192.

AN ACTIVE ANTENNA FOR ELF MAGNETIC FIELDS
John F. Sutton and Craig Spaniol (West Virginia State Coll., Charleston.) *In* West Virginia State Coll., Magnetic Earth Ionosphere Resonant Frequencies 15 Jan. 1994 21 p (For primary document see N94-25191 06-32)
Avail: CASI HC A03/MF A01

The work of Nikola Tesla, especially that directed toward world-wide electrical energy distribution via excitation of the earth-ionosphere cavity resonances, has stimulated interest in the study of these resonances. Not only are they important for their potential use in the transmission of intelligence and electrical power, they are important because they are an integral part of our natural environment. This paper describes the design of a sensitive, untuned, low noise active antenna which is uniquely suited to modern earth-ionosphere cavity resonance measurements employing fast-Fourier transform techniques for near-real-time data analysis. It capitalizes on a little known field-antenna interaction mechanism. Recently, the authors made preliminary measurements of the magnetic fields in the earth-ionosphere cavity. During the course of this study, the problem of designing an optimized ELF magnetic field sensor presented itself. The sensor would have to be small, light weight (for portable use), and capable of detecting the 5-50 Hz picoTesla-level signals generated by the natural excitations of the earth-ionosphere cavity resonances. A review of the literature revealed that past researchers had employed very large search coils, both tuned and untuned. Hill and Bostick, for example, used coils of 30,000 turns wound on high permeability cores of 1.83 m length, weighing 40 kg. Tuned coils are unsuitable for modern fast-Fourier transform data analysis techniques which require a broad spectrum input. 'Untuned' coils connected to high input impedance voltage amplifiers exhibit resonant responses at the resonant frequency determined by the coil inductance and the coil distributed winding capacitance. Also, considered as antennas, they have effective areas equal only to their geometrical areas. Author (revised)

WIDE BANDWIDTH DIFFERENTIAL AMPLIFIER Patent
Mark H. Berry, inventor (to Navy) and Debra J. Gookin, inventor (to Navy) 10 Aug. 1993 8 p Filed 21 Feb. 1991
(AD-D015985; US-Patent-5,235,455; US-Patent-Appl-SN-666125; US-Patent-Class-359-276) Avail: US Patent and Trademark Office

A differential amplifier for gigahertz bandwidth electrical signals using fiber optics and integrated optical devices has a differential gain which is

a function of the electrical to optical and optical to electrical conversion factors. The common mode rejection ratio of the differential amplifier at 1 GHz was greater than 30 dB and the common mode rejection ratio depended on the time difference between the differential amplifier inputs. A differential amplifier fabricated in accordance with this inventive concept could be used as an integrated module in radar and communications systems.

ON THE QUALITY OF SYNTHETIC SPEECH EVALUATION AND IMPROVEMENTS Ph.D. Thesis
Josephus Hubertus Eggen 1992 139 p Prepared in cooperation with Philips Gloeilampenfabrieken N.V., Eindhoven, Netherlands
(ETN-94-95298) Avail: CASI HC A07/MF A02

The human letter to sound conversion is modeled in a text to speech system. The purpose of the study is the assessment of some limitations of Linear Predictive Coding (LPC) as a scheme for speech analysis, manipulation and synthesis, and the exploration of ways to remove some of the drawbacks of LPC. The intelligibility of synthetic speech, which is an important attribute of speech quality, is studied. A perception experiment, in which an articulated test without noise and a Monosyllabic Adaptive Speech Interference Test (MASIT) were used to evaluate the intelligibility of nine different speech coding schemes, was conducted. The naturalness of synthetic speech is studied. The preservation of the identity of a speaker, as a feature of a high quality speech coding scheme, is studied. The relative importance of coded vocal tract and voice source information for perceived speaker identity is investigated. ESA

MODULATION AND SYNCHRONIZATION TECHNIQUE FOR MF-TDMA SYSTEM Final Report
Faris Faris, Thomas Inukai, and Soheil Sayegh 28 Jan. 1994 81 p
(Contract NAS3-25933; RTOP 506-72-21)
(NASA-CR-194448; E-8324; NAS 1.26:194448) Avail: CASI HC A05/MF A01

This report addresses modulation and synchronization techniques for a multi-frequency time division multiple access (MF-TDMA) system with onboard baseband processing. The types of synchronization techniques analyzed are asynchronous (conventional) TDMA, preambleless asynchronous TDMA, bit synchronous timing with a preamble, and preambleless bit synchronous timing. Among these alternatives, preambleless bit synchronous timing simplifies onboard multicarrier demultiplexer/demodulator designs (about 2:1 reduction in mass and power), requires smaller onboard buffers (10:1 to approximately 3:1 reduction in size), and provides better frame efficiency as well as lower onboard processing delay. Analysis and computer simulation illustrate that this technique can support a bit rate of up to 10 Mbit/s (or higher) with proper selection of design parameters. High bit rate transmission may require Doppler compensation and multiple phase error measurements. The recommended modulation technique for bit synchronous timing is coherent QPSK with differential encoding for the uplink and coherent QPSK for the downlink. Author (revised)

LINEAR AND NONLINEAR ADAPTIVE FILTERING AND THEIR APPLICATION TO SPEECH INTELLIGIBILITY ENHANCEMENT Ph.D. Thesis
Yu Hua Gu 1992 220 p
(ISBN-9-09-005342-5; ETN-94-95309) Copyright Avail: CASI HC A10/MF A03

The speech separation problem, where one speaker has to be selected from a signal being the sum of two speakers, is investigated: the situation where the noise itself is interference speech. Algorithms for an adaptive speech separation system were developed. The stochastic model theory to pitch contour estimation, with a specific application to the adaptive cochannel speech separation, is discussed. Linear and nonlinear adaptive filters for nonstationary signal processing are investigated. This includes the investigation of time-transform domain least mean square adaptive filters, as well as recursive least square types of algorithms with an adaptive size of the data window. General applications and simulations are described. A robust algorithm for simultaneous multipitch contour estimation is developed. After reviewing the human auditory pitch perception models and the previous research on this field, a general structure is proposed by using a pitch candidate estimator plus a pitch contour estimator based on a stochastic model. Algorithms associated with an adaptive speech separation system are described. ESA

DELAY-INSENSITIVE COMMUNICATION Ph.D. Thesis
Hubert Marie Jean-Lo Schols 1992 300 p
(ETN-94-95315) Copyright Avail: CASI HC A13/MF A03

Communication is called delay insensitive if it is delay safe and it has absence of transmission interference hazard. The communication model proposed is introduced. The communication model provides a clear separation between the interpretation of physical issues and the formalism. The communication behavior of a module and the communication of an interconnection are distinguished. The concept of computation interference hazard and a technique to transform other correctness concerns into absence of computation interference hazard are presented. The delay safe communication and the absence of computation interference hazard are discussed. The attention is focused on the communication behavior of mechanisms that communicate in a delay safe way. Within the context of delay safe communication, the absence of transmission interference hazard is introduced. The necessary and sufficient conditions for composition under some given correctness concerns and a method to calculate the composition under these conditions are given. ESA

DIFFUSION IN ELECTRONEGATIVE DISCHARGES WITH MAGNETIC FIELDS Ph.D. Thesis
David E. Bell 3 Dec. 1993 207 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273826; AFIT/DS/ENP/93-08) Avail: CASI HC A10

Electronegative plasmas are important in a variety of electric discharge applications, such as plasma reactors, negative ion sources, and even electropositive discharges when contaminated with an electronegative impurity. The need for an understanding of the processes and phenomena associated with these electronegative discharges has spurred the development of numerical simulations and models. While many of the devices incorporate various configurations of external magnetic fields, specific attention to the influence of the magnetic field on the discharge operating point, structure, and stability is lacking. To address this deficiency, a collisional model for diffusion in three-component plasmas with an applied magnetic field is developed; it is an extension of Schottky theory allowing for negative ions and a magnetic field. This study analyzes the effect of magnetic fields on diffusion in three-component plasmas; provides an analytic solution for the collisional model in a magnetic field; evaluates the validity of effective diffusion coefficients through an analysis of the afterglow; and provides a regime of validity for the model in terms of magnetic field strength by looking at the onset of anomalous diffusion. FORMAL VERIFICATION OF DIGITAL CIRCUITS DESCRIBED IN VHDL Ph.D. Thesis [VERIFICATION FORMELLE DES CIRCUITS DIGITAUX DECRITS EN VHDL]
Ashraf Mohammed El-F Salem 1992 132 p In FRENCH
(ETN-94-95165) Avail: CASI HC A07/MF A02

The formal verification of digital circuits described in VHSIC (very high speed integrated circuit) hardware description language (VHDL) is presented. VHDL is made processable by proof tools. A subset, called P-VHDL, dedicated to the description of combinatorial and synchronous sequential circuits is defined. The semantics of this subset is much simpler than the complete VHDL. The delta delay is replaced by a serialization function, and the time scale is chosen equal to the clock period. The use of the finite state machine as a formal model for the subset became possible. The finite state machine semantics is shown to represent the P-VHDL semantics. Based on this formal model, a proof oriented compiler for P-VHDL is written. A complete denotational semantic for P-VHDL is defined. Three different domains for the three values holders in the language are proposed: the variables, the signals, and the registers. Formal semantics for the VHDL timing constructs are given. The equivalence between these semantics and the VHDL informal operational semantics is proven. It is shown that semantics can form a basis for building a formal timing verifier. ESA

MICROWAVE ANALOG FREQUENCY DIVIDERS: DESIGN, MODELING AND REALIZATION Ph.D. Thesis - Toulouse Univ. [LES DIVISEURS ANALOGIQUES DE FREQUENCE MICRO-ONDES: MODELISATION, CONCEPTION ET REALISATION]
Hicham Amine 1993 137 p In FRENCH
(LAAS-93139; ETN-94-95191) Avail: CASI HC A07/MF A02

The design and modeling of microwave analog frequency dividers are investigated. Frequency domain and harmonic balance simulations of the transistor behavior, to permit self-biasing to be understood, are carried out. An approach to analog frequency dividers, based on the nonlinear feedback control of metal semiconductor field effect transistor in the forced oscillation mode, is proposed. The input signal is employed to control transistor gain. An optimal modeling of analog frequency dividers is proposed and tested by the use of time domain simulation. To validate this model, a 1/2 analog frequency divider is designed. Its measured performances were compared to the theoretical ones. A nonlinear model of analog frequency dividers noise conversion characteristics is accomplished. This model based on the conversion matrix method is used to evaluate the phase noise limit of our circuit. ESA

PICOSECOND HIGH PRESSURE GAS SWITCH EXPERIMENT
W. R. Cravey, E. K. Freytag, D. A. Goerz, P. Poulsen, and P. A. Pincosy Aug. 1993 6 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract W-7405-eng-48)
(DE93-040853; UCRL-JC-112339; CONF-930616-39) Avail: CASI HC A02/MF A01

A High Pressure Gas Switch has been developed and tested at LLNL. Risetimes on the order of 200 picoseconds have been observed at 1 kHz prf and 1 atmosphere pressures. Calculations show that switching closure times on the order of tens of picoseconds can be achieved at higher pressures and electric fields. A voltage hold-off of 1 MV/cm has been measured at 10 atmospheres and several MV/cm appears possible with the HPGS. With such high electric field levels, energy storage of tens of Joules in a reasonably sized package is achievable. Initial HPGS performance has been characterized using the WASP pulse generator at LLNL. A detailed description of the switch used for initial testing is given. Switch recovery times of 1-ms have been measured at 1 atmosphere. Data on the switching uniformity, voltage hold-off recovery, and pulse repeatability, is presented. In addition, a physics switch model is described and results are compared with experimental data. Modifications made to the WASP HV pulser in order to drive the HPGS will also be discussed. Recovery times of less than 1 ms were recorded without gas flow in the switch chambers. Low pressure synthetic air was used as the switch dielectric. Longer recovery times were required when it was necessary to over-voltage the switch. DOE

PROGRESS ON THE DESIGN OF A DATA PUSH ARCHITECTURE FOR AN ARRAY OF OPTIMIZED TIME TAGGING PIXELS
S. Shapiro, D. Cords, S. Mani (California Univ., Davis.), B. Holbrook (California Univ., Davis.), and E. Atlas (Adept IC Design, Oceanside, CA.) Jun. 1993 4 p Presented at the Workshop on Charged-Coupled Devices and Advanced Image Sensors, Waterloo, Ontario, 9-11 Jun. 1993
(Contracts DE-AC03-76SF-00515; DE-FG03-91ER-40674)
(DE93-041011; SLAC-PUB-6249; CONF-9306256-1) Avail: CASI HC A01/MF A01

A pixel array has been proposed which features a completely data driven architecture. A pixel cell has been designed that has been optimized for this readout. It retains the features of preceding designs which allow low noise operation, time stamping, analog signal processing, XY address recording, ghost elimination and sparse data transmission. The pixel design eliminates a number of problems inherent in previous designs, by the use of sampled data techniques, destructive readout, and current mode output drivers. This architecture and pixel design is directed at applications such as a forward spectrometer at the SSC, an e(sup +)e(sup -) B factory at SLAC, and fixed target experiments at FNAL. DOE

Walsh (National Inst. of Standards and Technology, Boulder, CO.) 1993 4 p Presented at the 13th International Conference on Magnet Technology, Victoria, Ontario, 20-24 Sep. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-000761; LA-UR-93-3391; CONF-930926-13) Avail: CASI HC A01

Results of the National High Magnetic Field Laboratory's program of characterization of materials and fabrication techniques used in the construction of high-field pulsed magnets are reported. High-field pulsed magnets require conductors with high mechanical strength (750 MPa or greater YS at 77K) and high electrical conductivity (70% IACS or greater at RT). Electrical insulation and resin systems for vacuum impregnation with high compressive strength (500 MPa at 77K) and moderate thermal conductivity (1kW/mK at 77K) are also required. Developments and future plans for the characterization of new magnet material systems are discussed. Testing result are reported: mechanical and fatigue testing, electrical conductivity testing and thermal expansion measurements of high strength, high conductivity conductors at cryogenic and room temperature, mechanical testing of a coil support material at cryogenic and room temperature, and thermal expansion and thermal conductivity tests of an electrical insulating system at cryogenic temperatures. DOE

CUSTOMIZABLE VLSI ARTIFICIAL NEURAL NETWORK CHIPS BASED ON A NOVEL TECHNOLOGY
C. Y. Fu, B. Law, G. Chapline, and D. Swenson (Naval Air Warfare Center, China Lake, CA.) 14 Sep. 1993 2 p Presented at the Government Microcircuit Applications Conference: Microelectronics in the New World Order, Las Vegas, NV, 9-12 Nov. 1992
(Contract W-7405-eng-48)
(DE94-001418; UCRL-JC-110366; CONF-921188-3) Avail: CASI HC A01/MF A01

The human cerebral cortex contains approximately 10(exp 11) neurons and 10(exp 14) synapses. It thus seems logical that any technology intended to mimic human capabilities should have the ability to fabricate a very large number of neurons and even larger numbers of synapses. This paper describes an implementation of hardware neural networks using highly linear thin-film resistor technology and an 8-bit binary weight circuit to produce customizable artificial neural network chips and systems. SIMPLE ESTIMATE OF STORED ENERGY AND CONDUCTOR INSULATION VOLTAGE-WITHSTAND REQUIREMENTS FOR ADVANCED SOLENOID MAGNET DESIGNS
S. W. Schwenterly and L. Dresner 1993 6 p Presented at the International Cryogenic Engineering Conference and International Cryogenic Materials Conference, Albuquerque, NM, 12-16 Jul. 1993
(Contract DE-AC05-84OR-21400)
(DE93-041048; CONF-930703-34) Avail: CASI HC A02/MF A01

Compact, lightweight, high-current-density superconducting magnets are of interest for many applications. Minimizing the area taken up by conductor stabilizer material and insulation can lead to high dump voltages if the magnet is protected by discharging it through an external resistor. The dump voltages per turn for circular solenoids are estimated for this situation, in terms of the well-known 'hotspot integral' H(Delta(T)), the maximum on-axis magnetic field B(sub z), and the stored energy E. The field and stored energy are calculated in terms of the coil geometry parameters alpha and beta. The results depend only on B(sub z), H(Delta(T)), and certain scaling factors, and are independent of the coil size. The relations give simple estimates of the average turn dump voltages for a coil of a given field and geometry which are useful for preliminary scoping studies during conceptual design of the magnet. DOE

LECTURES ON MAGNETOHYDRODYNAMICAL DRIVES

Villem Loigom 1993 69 p Prepared in cooperation with Tallinn Polytechnic Inst. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB93-224962; Rept-1993/39) Avail: CASI HC A04

The paper deals with nonconventional types of electrical machines and drives - magnetohydrodynamical (MHD) machines and drives. In cardinal it is based on the research conducted with participation of the author in Tallinn Technical University at the Institute of Electrical Drives and Power Electronics, where the use of magnetohydrodynamical motors and drives in the metallurgical and casting industries have been studied for a long time. Major research interests include the qualities and applications of the induction MHD-drives for set in the motion (pumping, turning, dosing, mixing, etc.) non-ferrous molten metals like Al, Mg, Sn, Pb, Na, K, and their alloys. The first part of the paper describes induction MHD motors and their electrohydraulical qualities. In the second part energy conversion problems are described. Also, on the basis of the analogy between electromechanical and electrohydraulical phenomenas, static and dynamic qualities of MHD drives with induction MHD machines are discussed. NTIS

STATIC IMAGE METHOD FOR COMPUTING THE ELECTRIC POTENTIAL DUE TO SOURCES IN A LAYERED SPHERE

J. C. E. Sten and R. J. Ilmoniemi Mar. 1993 24 p

(PB93-224970; ISBN-951-22-1455-5) Avail: CASI HC A03/MF A01

Following the approach of Neumann and Lindell, the authors derive an equivalent image line source that produces in a homogeneous medium the same electric field as a point source in a layered sphere. The image charge density function for the sphere with two interfaces of arbitrary radii and permittivities is solved analytically. Approximations are derived for the case when the two layers have nearly the same permittivities and for the case of thin outer layer. An image expression for the thin-layered sphere with three interfaces is developed. The authors suggest that a replacement of the image line by discrete point charges may be used to speed up computations of the electric potential on the scalp due to sources in the brain. In the lowest-order approximation, a single point source is placed at the center of gravity of the image line distribution. NTIS

TRANSIENT ANALYSIS OF CIRCUITS INCLUDING FREQUENCY-DEPENDENT COMPONENTS USING TRANSGYRATOR AND CONVOLUTION

P. Stenius, P. Heikkilae, and M. Valtonen Feb. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB93-225001; ISBN-951-22-1494-6) Avail: Issuing Activity (National Technical Information Service (NTIS))

A practical method for the transient analysis of circuits including frequency-dependent components, as well as the implementation of the method in a circuit-simulation software package called APLAC, has been presented. The main differences between the method and those previously presented are that the authors introduced the transgyrator and that the authors carefully minimized the number of mathematical operations needed in the analysis. These improvements finally make the method practical for usage in a circuit simulation software package intended for engineers. The implementation of the method in APLAC, using the NPort component model, consists of two separate C programming language source code files, together amounting to only 16 kB. Due to the object-oriented nature of all components written for APLAC, the coding time of the implementation was reduced considerably. NTIS

MULTIDISCIPLINARY SPECIFICATION AND DESIGN OF MICROELECTRONICS IN PRODUCTS [MULTIDISCIPLINAR SPECIFICEREN EN ONTWERPEN VAN MICROELEKTRONICA IN PRODUKTEN]

P. H. A. vanderPutten Jan. 1993 116 p In DUTCH

(EUT-93-E-269; ISBN-9-06-144269-9; ETN-94-94776) Avail: CASI HC A06/MF A02

The specification of products, incorporating information technology, requires the interaction with various disciplines. Complete specification may seem to be expensive, but it can reduce the number of iterations in the product development process. From the point of view of digital electronic design, interacting disciplines are shown, illustrated with examples. The report can be used as a source of ideas to improve the specification and design process. ESA

AMICAL: AN AID FOR ARCHITECTURAL SYNTHESIS AND EXPLORATION OF CONTROL CIRCUITS Ph.D. Thesis [AMICAL: UN ASSISTANT POUR LA SYNTHESE ET L'EXPLORATION ARCHITECTURALE DES CIRCUITS DE COMMANDE]

Inhag Park 1992 197 p In FRENCH

(ETN-94-95177) Avail: CASI HC A09/MF A03

AMICAL is an architectural synthesis system for control flow dominated circuits. A behavioral finite state machine specification, where the scheduling and register allocation were performed, is presented. An abstract architecture specification that may feed existing silicon compilers acting at the logic and register transfer levels is described. AMICAL consists of five main functions allowing automatic, interactive and manual synthesis, as well as the combination of these methods. These functions are a synthesizer, a graphics editor, a verifier, an evaluator, and a documentor. Automatic synthesis is achieved by algorithms that allocate both functional units, stored in an expandable user defined library, and connections. AMICAL also allows the designer to interrupt the synthesis process at any stage and make interactive modifications via a specially designed graphics editor. The user's modifications are verified and evaluated to ensure that no design rules are broken and that any imposed constraints are still met. A documentor provides the designer with status and feedback reports from the synthesis process. ESA

GENERATION OF MODULES FOR CONTROL COMMUNICATION CIRCUITS: A DESIGN STUDY USED IN THE FRAMEWORK OF THE SAFE VEHICLE PROMETHEUS Ph.D. Thesis [GENERATION DE MODULES DEDIES AUX CIRCUITS DE COMMUNICATION DE CONTROLE-COMMANDE: UNE ETUDE DE CONCEPTION APPLIQUEE DANS LE CADRE DE LA VOITURE SURE PROMETHEUS]

Imad Sabouni 1992 375 p In FRENCH

(ETN-94-95171) Avail: CASI HC A16/MF A03

The implementation of communication protocols on silicon integrated circuits for access control is considered. The field of application is the European PROMETHEUS (Program for European Traffic with Highest Efficiency and Unprecedented Safety) project. The design of communication circuits for network access control is discussed. The control type local network and the related protocols are analyzed. Market available communication controllers are presented. The functions and the architecture of network control systems are described and the interfaces with the host system are considered. A method based on the generation of modules for communication circuit's design is proposed. Examples of circuits generated for vehicle application networks are given. The feasibility of obstacle detection distributed system is investigated. ESA

MODULATION CHARACTERISTICS OF A HIGH-POWER SEMICONDUCTOR MASTER OSCILLATOR POWER AMPLIFIER (MOPA)

Donald Mitchell Cornwell, Jr. Washington Nov. 1992 115 p

(NASA-TM-104577; NAS 1.15:104577; Rept-93B00016) Avail: CASI HC A06/MF A02

A semiconductor master oscillator-power amplifier was demonstrated using an anti-reflection (AR) coated broad area laser as the amplifier. Under CW operation, diffraction-limited single-longitudinal-mode powers up to 340 mW were demonstrated. The characteristics of the far-field pattern were measured and compared to a two-dimensional reflective Fabry-Perot amplifier model of the device. The MOPA configuration was modulated by the master oscillator. Prior to injection into the amplifier, the amplitude and frequency modulation properties of the master oscillator were characterized. The frequency response of the MOPA configuration was characterized for an AM/FM modulated injection beam, and was found to be a function of the frequency detuning between the master oscillator and the resonant amplifier. A shift in the phase was also observed as a function of frequency detuning; this phase shift is attributed to the optical phase shift imparted to a wave reflected from a Fabry-Perot cavity. Square-wave optical pulses were generated at 10 MHz and 250 MHz with diffraction-limited peak powers of 200 mW and 250 mW. The peak power for a given modulation frequency is found to be limited by the injected power and the FM modulation at that frequency. The modulation results make the MOPA attractive for use as a transmitter source in applications such as free-space communications and ranging/altimetry. Author

ON THE ESTIMATION OF THE CORRELATION DIMENSION AND ITS APPLICATION TO RADAR REFLECTOR DISCRIMINATION Final Report
Kevin D. Barnett Dec. 1993 72 p
(Grant NAG1-928; RTOP 505-64-12-02)
(NASA-CR-4564; NAS 1.26:4564; DOT/FAA/RD-93/41; TR-073093-357OP; RSL-TR-17) Avail: CASI HC A04/MF A01

Recently, system theorists have recognized that low order systems of nonlinear differential equations can give rise to solutions which are neither periodic, constant, nor predictable in steady state, but which are nonetheless bounded and deterministic. This behavior, which was first described in the study of weather systems, has been termed 'chaotic.' Much study of chaotic systems has concentrated on analysis of the systems' phase space attractors. It has been recognized that invariant measures of the attractor possess inherent information about the system. One such measure is the dimension of the attractors. The dimension of a chaotic attractor has been shown to be noninteger, leading to the term 'strange attractor;' the attractor is said to have a fractal structure. The correlation dimension has become one of the most popular measures of dimension. However, many problems have been identified in correlation dimension estimation from time sequences. The most common methods for obtaining the correlation dimension have been least squares curves fitting to find the slope of the correlation integral and the Takens Estimator. However, these estimates show unacceptable sensitivity to the upper limit on the distance chosen. Here, a new method is proposed which is shown to be rather insensitive to the upper limit and to perform in a very stable manner, at least in the absence of noise. The correlation dimension is also shown to be an effective discriminant in distinguishing between radar returns resulting from weather and those from the ground. The weather returns are shown to have a correlation dimension generally between 2.0 and 3.0, while ground returns have a correlation dimension exceeding 3.0. Author (revised)

FABRICATION OF SUB-40-nm p-n JUNCTIONS FOR 0.18 MICRON MOS DEVICE APPLICATIONS USING A CLUSTER-TOOL-COMPATIBLE, NANOSECOND THERMAL DOPING TECHNIQUE
K. H. Weiner and A. M. McCarthy 20 Sep. 1993 8 p Presented at the Society of Photo-Optical Instrumentation Engineers (SPIE) Symposium on Microelectronics Processing, Monterey, CA, 27-29 Sep. 1993
(Contract W-7405-eng-48)
(DE94-001608; UCRL-JC-114003; CONF-9309264-1) Avail: CASI HC A02/MF A01

In this paper, we introduced an alternative deep-submicrometer doping technology, Projection Gas Immersion Laser Doping (P-GILD). Representing the marriage of lithography and diffusion, P-GILD is a resistless, step-and-repeat doping process that utilizes excimer laser light patterned by a dielectric reticle to selectively heat and, thereby, dope regions of an integrated circuit. Results of physical and electrical characterization are presented for ultra-shallow p(sup +) (minus)n and n(sup +) (minus)p junctions produced by gas immersion laser doping (GILD), a phenomenologically identical technique that utilizes an aluminum contact mask rather than a dielectric reticle to pattern the beam. Junctions produced using GILD exhibit uniformly-doped, abrupt impurity profiles with no apparent defect formation in the silicon. Electrically, sheet and contact resistivities of the ultra-shallow junctions are less than 100(Omega)/sheet and 1 x 10(exp -6) (Omega)*sq cm, respectively, while n(sup +) (minus)p and p(sup +) (minus)n diodes exhibit nearly ideal forward bias behavior and reverse leakage current densities less than 5 nA/sq cm at -5V. Uniformity of both diode characteristics and sheet resistance for junctions produced by the step-and-repeat process is also shown to be better than (plus minus)5% across a 4-inch wafer. DOE

THE ELECTRONICS QUALITY/RELIABILITY CENTER: LESSONS LEARNED FROM PARTNERING WITH INDUSTRY
Theodore A. Dellin 1993 4 p Presented at the 1993 Government Microcircuit Application Conference, New Orleans, LA, 1-4 Nov. 1993
(Contract DE-AC04-94AL-85000)
(DE94-001501; SAND-93-2100C; CONF-9311101-4) Avail: CASI HC A01/MF A01

The government electronics community faces the exciting challenge of entering into new types of partnerships with the commercial electronics industry. Past interactions were based primarily on the needs of government. Future interactions will be based more on the needs of industry, particularly its need to be competitive in commercial products. The most successful groups will be those most adept at forming this new type of 'win-win' partner. Fortunately, both government and industry want to make these new partnerships successful. The government is driven by the necessity of establishing a common government/commercial manufacturing base and the desire to support U.S. competitiveness. Industry is driven by the need to partner with government to remain competitive. Unfortunately, there are no detailed guides available to help government electronics groups and their sponsors in the Administration and Congress cross this uncharted terrain. The purpose of this paper is to share some 'lessons learned' from the experiences of a government electronics group that has been active in establishing these new types of partnerships with industry. It is our hope that by sharing these lessons we will make it easier for other government groups to work with the commercial industry. DOE

US-Patent-Class-257-528) Avail: US Patent and Trademark Office

A bistable switching element is made of a material whose electrical resistance reversibly decreases in response to intercalation by positive ions. Flow of positive ions between the bistable switching element and a positive ion source is controlled by means of an electrical potential applied across a thermal switching element. The material of the thermal switching element generates heat in response to electrical current flow therethrough, which in turn causes the material to undergo a thermal phase transition from a high electrical resistance state to a low electrical resistance state as the temperature increases above a predetermined value. Application of the electrical potential in one direction renders the thermal switching element conductive to pass electron current out of the ion source. This causes positive ions to flow from the source into the bistable switching element and intercalate the same to produce a non-volatile, low resistance logic state. Application of the electrical potential in the opposite direction causes reverse current flow which de-intercalates the bistable logic switching element and produces a high resistance logic state.

US-Patent-Class-257-486; US-Patent-Class-257-506) Avail: US Patent and Trademark Office

The invention relates to planar varactor frequency multiplier devices with a heterojunction blocking barrier for near millimeter wave radiation of moderate power from a fundamental input wave. The space charge limitation of the submillimeter frequency multiplier devices of the BIN(sup +) type is overcome by a diode structure comprising an n(sup +) doped layer of semiconductor material functioning as a low resistance back contact, a layer of semiconductor material with n-type doping functioning as a drift region grown on the back contact layer, a delta doping sheet forming a positive charge at the interface of the drift region layer with a barrier layer, and a surface metal contact. The layers thus formed on an n(sup +) doped layer may be divided into two isolated back-to-back BNN(sup +) diodes by separately depositing two surface metal contacts. By repeating the sequence of the drift region layer and the barrier layer with the delta doping sheet at the interfaces between the drift and barrier layers, a plurality of stacked diodes is formed. The novelty of the invention resides in providing n-type semiconductor material for the drift region in a GaAs/AlGaAs structure, and in stacking a plurality of such BNN(sup +) diodes stacked for greater output power with and connected back-to-back with the n(sup +) GaAs layer as an internal back contact and separate metal contact over an AlGaAs barrier layer on top of each stack.

US-Patent-Class-429-218; Int-Patent-Class-H01M-10/48) Avail: US Patent and Trademark Office

A cathode additive is provided for protecting an ambient temperature secondary lithium cell from overcharging or overdischarging. The cathode additive is chosen to create an upper voltage plateau which is slightly higher than a characteristic charge cutoff voltage of the cathode of the cell. The cathode additive additionally creates a lower voltage plateau which is slightly lower than the characteristic discharge cutoff voltage of the cell. Preferably, the cathode additive is a transition metal oxide or a sulfide and may, for example, include a mixture of Li2Mn2O4 and Li(0.1)MoO2. GENERALIZED THREE-DIMENSIONAL SIMULATION OF FERRULED COUPLED-CAVITY TRAVELING-WAVE-TUBE DISPERSION AND IMPEDANCE CHARACTERISTICS

Joseph W. Maruschek (Ohio Aerospace Inst., Brook Park.), Carol L. Kory (Analex Corp., Brook Park, OH.), and Jeffrey D. Wilson Washington Nov. 1993 15 p
(RTOP 506-72-00)
(NASA-TP-3389; E-7977; NAS 1.60:3389) Avail: CASI HC A03/MF A01

The frequency-phase dispersion and Pierce on-axis interaction impedance of a ferruled, coupled-cavity, traveling-wave tube (TWT), slow-wave circuit were calculated using the three-dimensional simulation code Micro-SOS. The utilization of the code to reduce costly and time-consuming experimental cold tests is demonstrated by the accuracy achieved in calculating these parameters. A generalized input file was developed so that ferruled coupled-cavity TWT slow-wave circuits of arbitrary dimensions could be easily modeled. The practicality of the generalized input file was tested by applying it to the ferruled coupled-cavity slow-wave circuit of the Hughes Aircraft Company model 961HA TWT and by comparing the results with experimental results. ARC ELECTRODE INTERACTION STUDY Final Report

X. Zhou, D. Berns, and J. Heberlein 31 Jan. 1994 26 p Original contains color illustrations
(Grant NAG3-1332)
(NASA-CR-195096; NAS 1.26:195096) Avail: CASI HC A03/MF A01; 7 functional color pages

The project consisted of two parts: (1) the cathode interaction studies which were a continuation of previous work and had the objective of increasing our understanding of the microscopic phenomena controlling cathode erosion in arc jet thrusters, and (2) the studies of the anode attachment in arc jet thrusters. The cathode interaction studies consisted of (1) a continuation of some modeling work in which the previously derived model for the cathode heating was applied to some specific gases and electrode materials, and (2) experimental work in which various diagnostics was applied to the cathode. The specific diagnostics used were observation of the cathode tip during arcing using a Laser Strobe Video system in conjunction with a tele-microscope, a monochromator with an optical multichannel analyzer for the determination of the cathode temperature distribution, and various ex situ materials analysis methods. The emphasis of our effort was shifted to the cathode materials analysis because a parallel project was in place during the second half of 1993 with a visiting scientist pursuing arc electrode materials studies. As a consequence, the diagnostic investigations of the arc in front of the cathode had to be postponed to the first half of 1994, and we are presently preparing these measurements. The results of last year's study showed some unexpected effects influencing the cathode erosion behavior, such as increased erosion away from the cathode tip, and our understanding of these effects should improve our ability to control cathode erosion. The arc jet anode attachment studies concentrated on diagnostics of the instabilities in subsonic anode attachment arc jet thrusters, and were supplemental measurements to work which was performed by one of the authors who spent the summer as an intern at NASA Lewis Research Center. A summary of the results obtained during the internship are included because they formed an integral part of the study. Two tasks for 1994, the diagnostics of the anode closure phenomenon, and the use of arc jet thrusters for the deposition of c-BN, are being prepared. Author (revised)

SPATIAL FREQUENCY MULTIPLIER WITH ACTIVE LINEARLY TAPERED SLOT ANTENNA ARRAY

Rainee N. Simons (Sverdrup Technology, Inc., Brook Park, OH.) and Richard Q. Lee Feb. 1994 6 p Prepared for presentation at the IEEE MTT-S International Microwave Symposium, San Diego, CA, 23-28 May 1994; sponsored by IEEE
(Contract NAS3-25266; RTOP 506-44-2C)
(NASA-TM-106494; E-8060; NAS 1.15:106494) Avail: CASI HC A02/MF A01

A frequency multiplier with active linearly tapered slot antennas (LTSA's) has been demonstrated at the second harmonic frequency. In each antenna element, a GaAs monolithic microwave integrated circuit (MMIC) distributed amplifier is integrated with two LTSA's. The multiplier has a very wide bandwidth and large dynamic range. The fundamental-to-second harmonic conversion efficiency is 8.1 percent. The spatially combined second harmonic signal is 50 dB above the noise level. The design is suitable for constructing a large array using monolithic integration techniques. Author

COMPUTER MODELING OF PLASMA FLOW SWITCHES-HIGH CURRENT SWITCHING ON PROCYON
R. L. Bowers, A. E. Greene, D. L. Peterson, and N. F. Roderick (New Mexico Univ., Albuquerque.) 1993 13 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract W-7405-eng-36)
(DE93-040189; LA-UR-93-3070; CONF-930616-38) Avail: CASI HC A03/MF A01

Procyon is a high explosive driven pulsed power system designed to drive plasma z-pinch experiments to the 1-MJ level. Details of this system are provided elsewhere in these proceedings. The final switching stage of the Procyon system is a plasma flow switch (PFS). Our most recent experiment (April 29, 1993) included a full power test of the PFS designed for the Procyon system. In this test the Mark IX explosively driven generator delivered 22 MA of current to the storage inductor. The slight flux compression that occurs in the explosively formed fuse (EFF) opening switch increased this current to 24.5 MA. The EFF then opened and switched 16.5 MA to the PFS. The PFS switched 15.5 MA to the load region (the slot that will contain an imploding foil liner in future experiments) with a 10-90 rise time of 500 ns. In this present paper we discuss the computer modeling we have done on this Procyon plasma flow switch. In the next section we discuss the design of the Procyon switch and preshot calculations. Although the April 1993 experiment was quite successful there were significant surprises in the performance of the PFS. In the last sections of this paper we discuss the work we have done in understanding the results of this experiment and the conclusions that we have reached to date. DOE

CROSSTALK ANALYSIS OF SYNCHRONOUS AND ASYNCHRONOUS OPTICAL CHIP INTERCONNECTS WITH DIRECT DETECTION M.S. Thesis
Rena M. Loesch Sep. 1993 96 p
(AD-A273261) Avail: CASI HC A05/MF A01

This thesis provides a crosstalk analysis of optical chip interconnects via single-mode waveguides with synchronous transmission and asynchronous transmission. This crosstalk model is general and can be used for any type of waveguide network. Three cases of laser sources will be considered: (1) each channel operates with an independent laser sources, (2) all laser sources have the same mean wavelength but with different phase noise processes, and (3) all laser sources are identical with the exception of the initial phases. The analysis takes into account the coupling-induced crosstalks between adjacent waveguides, the laser linewidth, the shot noise, the dark current generated by the photodiode, and the post-detection thermal noise. Bit error probabilities versus received peak powers are presented together with power penalties. DTIC

FIELD EMITTER ARRAY MEMORY DEVICE Patent
Henry F. Gray, inventor (to Navy) 27 Jul. 1993 7 p Filed 2 Jul. 1990
(AD-D016015; US-Patent-5,231,606; US-Patent-Appl-SN-546817; US-Patent-Class-365-225.6) Avail: US Patent and Trademark Office

A field emitter array memory device having two or more collector electrodes, an extraction electrode, at least one deflector electrode, and at least one electron field emitter is disclosed. The field emitter array memory circuit has bias voltages for collector electrodes, for at least one deflector electrode and for the extraction electrode. In a preferred embodiment of the invention, first and second input signal voltages selectively applied to first and second deflector electrodes selectively switch the flow of electrons emitted from an electron field emitter from a first collector electrode to a second collector electrode and vice versa. A latched memory output is also included. Electron flow from the electron field emitter to one of the first and second collector electrodes is maintained until a signal voltage is applied to a deflector electrode to cause the electron flow to deflect from one collector electrode to the other collector electrode. CARBON SUPERCAPACITORS
F. M. Delnick 1993 14 p Presented at the Symposium on Science of Advanced Batteries, Cleveland, OH, 8-9 Nov. 1993
(Contract DE-AC04-94AL-85000)
(DE94-002652; SAND-93-2421C; CONF-9311115-1) Avail: CASI HC A03/MF A01

Carbon supercapacitors are represented as distributed RC networks with transmission line equivalent circuits. At low charge/discharge rates and low frequencies these networks approximate a simple series R(sub ESR)C circuit. The energy efficiency of the supercapacitor is limited by the voltage drop across the ESR. The pore structure of the carbon electrode defines the electrochemically active surface area which in turn establishes the volume specific capacitance of the carbon material. To date, the highest volume specific capacitance reported for a supercapacitor electrode is 220 F/cm(exp 3) in aqueous H2SO4 and approximately 60 F/cm(exp 3) in nonaqueous electrolyte. DOE

DESIGN AND TESTING OF UBITRON AMPLIFIER TUBES Final Technical Report
Dean Pershing Oct. 1993 199 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-85-C-2141)
(AD-A273297; MRC/WDC-R-316) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The components for a single-stage/single-pass Ku band ubitron amplifier were designed, constructed, and tested. Notable features of this device include a high quality electron beam and circularly polarized microwave and wiggler fields. Stable operation of the assembled amplifier was achieved during initial testing using a modified SLAC klystron electron gun. In addition, amplifier and oscillator operation was measured using an unusual rippled beam parameter regime. The ubitron was only operated in the small signal regime; no large signal measurements (e.g. saturation) were attempted. In this regime, peak gains of 19 dB were measured with greater than 25% bandwidth. The general performance characteristics are in reasonable agreement with theoretical predictions, although there are discrepancies between the measured and theoretical gain vs. frequency profiles. More work is needed to determine whether this is a deficiency in the model or if operational characteristics are not adequately well known, e.g. details of the wiggler field profile. An investigation of ubitron amplifier performance limits, including performance enhancement through system parameter tapering, should be possible with operation at the design voltage using the advanced electron gun. THE 5TH ENGINEERING FOUNDATION CONFERENCE: ADVANCED HETEROSTRUCTURE TRANSISTORS Final Report
Dec. 1992 22 p Conference held in Kona, HI, 29 Nov. - 4 Dec. 1992
(Contract N00014-93-1-0125)
(AD-A273508) Avail: CASI HC A03/MF A01

The session on Heterostructure FET's concentrated on power devices. L. Eastman of Cornell University reported 5 W at 4 GHz with 70% efficiency and 15 dB of gain from a GE device, and 1 W at 4 GHz with 80% efficiency from Raytheon. J. Wolter described avalanche breakdown via DX centers in AlGaAs, and theoretical optimization of deep submicron HFET's for power handling was reported by M. Das. Silicon-germanium HBT's have made several improvements. K. Ismail of Cairo University and IBM showed how the Si/SiGe band lineup can be changed by strain relief, producing barriers to electrons as well as holes. Very high mobilities were reported, and the claim was made that SiGe devices at 77 K may be operationally equivalent to III-V devices at room temperature. This would clearly be important given the fabrication advantages of silicon-based technologies. Silicon-germanium HBT technology seemed to be too complex to insert into digital processes, but SiGe FET's may not be. Resonant-tunneling diodes (RTD's) have been combined into potentially multigigahertz shift-register circuits by G. Sollner at MIT Lincoln Laboratory. R. Behringer of AT&T reported experiments in optically controlled patterned growth of Na gratings using a technique that may be applicable to imaging In or Ga atoms during MBE growth. The consequences of optical phonon propagation in AlGaAs structures were discussed experimentally by G. Maracas of Motorola and L. Eastman of Cornell, and theoretically by K. W. Kim of the University of North Carolina. Interesting effects occur because optical phonons in GaAs cannot propagate in AlAs and conversely. HBT papers from III-V materials dwelt on materials issues nad centered on carbon doping and its associated strain and activation. Derived from text

COMPARATIVE M-H CHARACTERISTICS OF 1-5 AND 2-17 TYPE SAMARIUM-COBALT PERMANENT MAGNETS TO 300 C
Janis M. Niedra Mar. 1994 8 p
(Contract NAS3-25266; RTOP 583-02-21)
(NASA-CR-194440; E-8481; NAS 1.26:194440) Avail: CASI HC A02/MF A01

Recent consideration of the use of permanent magnets in space power converters at heat rejection temperatures exceeding 250 C and in miniature high temperature actuators is supporting a search for permanent magnets resistant to demagnetizing forces at high temperature. The present paper investigates the short-term demagnetization resistance to applied bucking fields and at temperatures up to 300 C of SmCo5 type magnets, in the form of 1-cm cubes, from several commercial sources. Quasistatic, 2nd quadrant M-H data taken at selected temperatures are the source of derived plots which are then compared to similar data for previously tested Sm2Co17 type magnets. The 1-5 magnet remanence tends to be about 1.5 kG below that of the 2-17 magnets throughout the temperature range. However, the intrinsic coercivities and M-H curve 'knee-fields' seen in particular 1-5 magnets were considerably above those seen previously in the 2-17 magnets. This superior resistance to demagnetizing fields attainable in 1-5 magnets is also illustrated by safe operating area plots based on the knee-field, the magnetic induction swing and temperature. Comments are made on the possibility that a remanence versus knee-field tradeoff can make 1-5 material competitive with 2-17 in applications where a magnet has to withstand large bucking fields at high temperature. METHOD FOR FABRICATING SELF-ALIGNED GATE DIFFUSED JUNCTION FIELD EFFECT TRANSISTOR Patent
Richard Nguyen, inventor (to Navy) and Charles A. Hewett, inventor (to Navy) 28 Sep. 1993 7 p Filed 28 Aug. 1992
(AD-D015975; US-Patent-5,248,626; US-Patent-Appl-SN-937916) Avail: US Patent and Trademark Office

A method for fabricating a self-aligned, gate diffused junction field effect transistor is provided which includes the steps of forming an n-type layer on an indium phosphide, semi-insulating substrate; forming spaced apart source/drain metal contacts on the n-type layer; forming a metal gate on the n-type layer between the spaced apart source/drain contacts, where the metal gate is insulated from the source/drain contacts and includes a metallic p-type dopant material; and forming a p-type region in the n-type layer beneath the metal gate so that the gate contact and the p-type region have coincident boundaries with respect to each other at the surface of the n-type layer. The method may also be employed to manufacture a bipolar transistor by allowing the self-aligned and diffused p-type region to extend through the n-type layer to the semi-insulating substrate. DTIC

SOLID STATE TIME BASE CORRECTOR (TBC) Patent
John L. Piri, inventor (to Navy) and Marc L. Moulton, inventor (to Navy) 3 Aug. 1993 18 p Filed 10 Apr. 1985
(AD-D015981; US-Patent-5,233,420; US-Patent-Appl-SN-721821; US-Patent-Class-358-149) Avail: US Patent and Trademark Office

Synchronization of remotely originating video signals to a standardized frequency is assured on a field-by-field basis. The video signals are digitized, multiplexed, and stored in fields in accordance with their horizontal and vertical sync signals. A reading out of storage, demultiplexing, and reconversion to video signals at the standardized frequency on a field-by-field basis allows a real time presentation to standard equipments at a standardize rates. DTIC

MOS ANALOG MEMORY WITH INJECTION CAPACITORS Patent
Randy L. Shimabukuro, inventor (to Navy), Michael E. Steward, inventor (to Navy), Patrick A. Shoemaker, inventor (to Navy), and Graham A. Garcia, inventor (to Navy) 12 Oct. 1993 15 p Filed 9 Jan. 1991
(AD-D015990; US-Patent-5,253,196; US-Patent-Appl-SN-639500; US-Patent-Class-365-45) Avail: US Patent and Trademark Office

An integrated circuit memory element is capable of storing analog information. The memory value can be increased and decreased incrementally with no knowledge of the current state and may be stored for a long period of time. Analog memory information is stored as an electrical charge on a floating gate structure and modification of this information is accomplished by the use of hot-carrier injection to transport electrons off of as well as onto the floating gate (to erase as well as to program electrically). Charge is written onto and off of the gate by injection capacitors in deep depletion and is accomplished by having the floating gate contiguous with a piece of crystalline p-type silicon, in which a deep-depletion region may be formed so that hot electrons may be ejected from (ejected off of) the floating gate structure through the surrounding insulating oxide, and having the floating gate structure capacitively coupled to a second piece of crystalline silicon from which electrons may be injected onto the floating gate structure. The novelty of the invention resides in the utilization of avalanche injection of electrons onto and off of the floating gate using injection capacitors. This requires far less current and is more symmetric than the original dual polarity MOS analog memory devices of the prior art. DTIC

PLANET: A HIERARCHICAL NETWORK SIMULATOR Ph.D. Thesis
Thomas Andreas Maria Kevenaar 1993 143 p
(Contract IC-EEL-88.036)
(ISBN-9-09-005693-9; ETN-94-95328) Copyright Avail: CASI HC A07/MF A02

A Piecewise Linear (PL) network simulator called PLANET that can be used in a hierarchical design environment is presented. The most important descriptions of PL functions are compared. A method for generating a PL model automatically for an arbitrary combinatorial logic function is developed. Almost every aspect of the simulator is treated. A numerical integration method that fits in with the hierarchical structure of the simulation tree is given. The simulator is extended by a network description compiler to furnish it with a flexible interface which is almost mandatory if the simulator must be interfaced with an automatic synthesis unit. This is explained by describing a coupling with the synthesis tool. Some simulation examples are given. ESA

ON THE CHARACTERIZATION AND OPTIMIZATION OF HIGH-SPEED SILICON BIPOLAR TRANSISTORS Ph.D. Thesis
Paul Jacques vanWijnen 1992 272 p Prepared in cooperation with Philips Research Labs.-Signetics, Sunnyvale, CA, and Philips Gloeilampenfabrieken N.V., Eindhoven, Netherlands Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95367) Copyright Avail: CASI HC A12

An on wafer high frequency measurement technique and its application to accurate small signal characterization and optimization of high speed bipolar transistors is presented. The evolution of high speed bipolar transistors and the need for accurate tools for device characterization, device modeling and parameter extraction, and device optimization are discussed. An introduction of small signal analysis and two port parameters is given. The scattering or s parameters and their relationships to the more conventional z, y, h, g, a and b Kirchhoff based two port parameter sets are derived. The custom high frequency small signal measurement setup, assembled from commercially available components, is described. The basic measurement methodology developed in order to account for these errors in a consistent manner is discussed. In particular, how this general methodology can be specialized to apply to on wafer measurements, is also discussed. High frequency characterization of small geometry bipolar transistors up to 18 GHz at various bias conditions is discussed. The device optimization is studied in the context of improving the high frequency performance. The use of a localized collector implant to improve the performance of polysilicon transistors is considered. ESA

IMPROVED MAGNETOSTRICTIVE TRANSDUCER DRIVE ELEMENTS ACHIEVED BY REDUCTION OF CRYSTALLINE DEFECTS AND IMPROVED CRYSTALLINE ORIENTATION Final Report
Dale McMasters 29 Oct. 1993 25 p
(Contract N00014-92-C-0210)
(AD-A273391) Avail: CASI HC A03/MF A01

The discovery of the 'giant' magnetostrictive rare earth-iron alloys in the 1970's was a direct result of the efforts initiated at DOD's Naval Surface Warfare Center (NSWC), Silver Spring, MD in conjunction with DOE's Ames Laboratory (AL), Ames, IA. This research into these new materials was specifically targeted for the development of low frequency, high power transducers for underwater sonar systems. The most technologically advanced of these materials is TERFENOL-D, Tb(3)Dy(7)Fe(1.9-1.95) an intermetallic compound consisting of iron (Fe) and the rare earth metals terbium (Tb), and dysprosium (Dy). Because of the advantages over existing transducer materials, the use of TERFENOL-D as a transducer drive element is expanding into a broad range of commercial applications and advanced defense systems. One of the disadvantages is the cost of these drivers, primarily due to the terbium and dysprosium raw materials. DTIC

MESOSCOPIC PHENOMENA IN METALLIC POINT CONTACTS Ph.D. Thesis
Philippus Antonius M Holweg 1992 143 p Sponsored by Stichting voor Fundamenteel Onderzoek der Materie, Netherlands
(ETN-94-95371) Avail: CASI HC A07/MF A02

Electron transport studies on microfabricated metallic point contacts, ultrasmall devices with a typical size of 10 nm, are described. Point contacts, consisting of a very small bridge between two metal films, were fabricated with a typical diameter of 10 nm. By varying the purity of the metal applied in these point contacts, the constriction diameter is much smaller than the elastic and inelastic electron mean free path (ballistic transport) or comparable to the elastic mean free path (quasi ballistic transport). Two new phenomena were observed in the ballistic point contacts. These are two level fluctuations of the conductance as a function of time, and time independent aperiodic fluctuations of the conductance as a function of voltage and magnetic field. These are both sample specific, mesoscopic phenomena, because they are very sensitive to the precise location of defects around the constriction. ESA

CONTRIBUTION TO THE STUDY OF HF CONVERTERS RADIATED DISTURBANCES Ph.D. Thesis [CONTRIBUTION A L'ETUDE DES PERTURBATIONS RAYONNEES PAR LES CONVERTISSEURS H.F.]
Antoine Puzo 1992 213 p In FRENCH
(ECL-92-34; ETN-94-95200) Avail: CASI HC A10/MF A03

The perturbations originated from switching on or off circuits which make up converters are investigated. In order to study and quantify the phenomena resulting from the ways radiated interferences are generated, the study centered on the switching circuits which represent the main switching modes: the forced switching, the zero current switching and the zero voltage switching. The evolution of the radiated electric and magnetic fields were determined. These fields were calculated from the voltage and the current produced in the different loops of the converter device. The importance of the parasitic components which constitute the active and the passive elements, as well as the wiring, on creating and transmitting the radiated interferences was stressed. This analysis was made from a theoretical study and was validated by a numerical simulation. The bases for the simulation of conducted and radiated perturbations were established. The study of the mechanics used for the transmission of radiated interference was performed by modifying the electric and topological quantities of the static converters used. ESA

CsI(Tl)-PHOTODIODE DETECTORS FOR SPECTROSCOPY AT LOW RADIATION LEVELS

Rainer Kotthaus Oct. 1992 21 p Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(MPI-PhE/92-22; ETN-94-95113) Copyright Avail: CASI HC A03

Some aspects of CsI(Tl) photodiode detectors relevant for applications in low level radiation spectroscopy in the MeV energy range are studied. The attention is focused on a search for the lepton number violating neutrinoless double beta decay of Mo-100. Energy resolutions of slightly less than 100 keV, limited by electronic noise, were obtained for crystal masses up to more than 3 kg. The improved energy resolution facilitates a sensitive investigation of crystal contaminations with nuclides of the Th and U chains by spectroscopic analysis of alpha decays. The cleanest crystal was free of U and Th contaminations at the detection limit of 0.27 alpha decays per kg and per hour, a radiopurity satisfactory for applications in low level spectroscopy. ESA

STUDY OF A SYSTEM FOR PRODUCING A PULSED MAGNETIC FIELD (B 2T) WITH A FREQUENCY OF 50 Hz [ETUDE D'UN SYSTEME PRODUISANT UN CHAMP MAGNETIQUE PULSE (B 2T) AVEC UNE FREQUENCE DE 50 HZ]

P. Lehmann and G. Buderer 7 Feb. 1992 24 p In FRENCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(ISL-N-601/92; ETN-94-95116) Avail: CASI HC A03

An electromagnetic circuit and a synchronized switch designed to generate a 2 T magnetic field are described. The aim was to produce the 2 T magnetic field with a frequency of 50 Hz in 25 microseconds. The equations characterizing several axially symmetric magnetic coils are given. The electric circuit of a magnet of eleven spirals and containing two silver coils is described. It is shown that a 2 T magnetic field can be obtained at the coil's axis by using a 1382 micro-F capacitor, a 36 milli-ohms resistance, and applying 220 V. The proposed system requires a 10 cu cm/s water flow for cooling the coil during the time gap between two pulses. ESA

SHIELDED COIL ELECTRODYNAMIC PROPULSION (SCEP). A FEASIBILITY STUDY M.S. Thesis

Richard J. Ladouceur Dec. 1993 112 p

(AD-A273824; AFIT/GSO/ENY/93D-6) Avail: CASI HC A06/MF A02

This study investigated Shielded Coil Electrodynamic Propulsion (SCEP). The use of the earth's magnetic field as a propulsion source has been previously investigated. It was found that a significant amount of power and long conductors were required. A more compact propulsion concept which requires significantly less power is proposed. This concept relies on the feasibility of significantly reducing the magnetic force induced by the earth's magnetic field on selected segments of a coil. An experiment design to support the theoretical findings was conducted. The experiment results support the theoretical model. DTIC

A MULTIGRID MULTIBLOCK SOLVER FOR COMPRESSIBLE TURBULENT FLOW
Hans G. M. Kuerten and Bernard J. Geurts Mar. 1993 16 p
(MEMO-1125; ETN-94-94761) Avail: CASI HC A03/MF A01

A multigrid multiblock method for compressible turbulent flow simulations is described and results obtained from calculations on a two element airfoil are presented. A vertex based spatial discretization method and explicit multistage Runge-Kutta time stepping are used. The slow convergence of a single grid method makes the multigrid method, which yields a speed up with a factor of about 12.5, indispensable. The numerical predictions are in good agreement with experimental results. The convergence of the multigrid process is shown to depend considerably on the ordering of the various loops. If the block loop is put inside the stage loop, the process converges more rapidly than if the block loop is situated outside the stage loop in the case where a three stage Runge-Kutta method is used. If a five stage scheme is used, the process does not converge in the latter block ordering. The process based on the five stage method is about 60% more efficient than with the three stage method.

Avail: CASI HC A03/MF A01

Turbulent flow fields are studied with emphasis on calculation of oscillation terms. Two methods of computation of Reynolds stresses, based on the Boussinesq approximation or the transport equations, are presented. The model of Launder-Spalding was used for calculation of turbulent energy and dissipation rate. Experimental procedures, based on laser Doppler measurements, are proposed for both methods. An experimental facility for estimation of turbulent energy is described. A two channel argon laser Doppler system was used with two photomultipliers for converting optical signals into electrical ones. After an electronic frequency shift of both photomultiplier signals, an amplification and a band pass filtration, the Doppler bursts were processed by two counters and a coincidence filtering was carried out in a buffer interface with both signals. The coupling of the laser Doppler anemometer facility to the oscillating flow process was achieved using a phase detector made of a hot wire anemometer and a filter for the analog signal.

C. A. Poensgen and H. E. Gallus *In* Tech. Univ. Berlin, Experimental Methods in Separated Flows 1991 p 15-29 In GERMAN (For primary document see N94-22852 06-34)
Avail: CASI HC A03/MF A01

The development of flow separation between the hub wall and the blade suction side in an axial compressor annular cascade is examined with several measurement techniques. The flow was first assumed to be stationary; separation could be estimated with flow visualization and pneumatic pressure measurements on lateral walls and blade surfaces were carried out for evaluating flow losses in the cascade. Measurements at airfoil surfaces with hot wire probes and hot film sensors gave information about the development of the blade boundary layer. The influence of the unstationary flow on the development of airfoil boundary layers and the separation at the hub with dependence of the aerodynamic loading is studied. Cylindrical bars were used instead of a real blading in order to obtain typical wakes without potential interactions between rotor and stator. Experimental examinations similar to the one described for the steady flow were carried out. It is found that flow losses increase in the airfoil boundary layer while they drop to the hub separation. By and large, the total losses are found to be lower with unsteady flow.

PRESSURE OSCILLATION MEASUREMENTS IN TURBULENT FLOWS [DRUCKSCHWANKUNGSMESSUNGEN IN TURBULENTEN STROEMUNGEN]

M. Nasseri and W. Nitsche *In its* Experimental Methods in Separated Flows 1991 p 30-43 In GERMAN (For primary document see N94-22852 06-34)

Avail: CASI HC A03/MF A01

Rotation symmetric internal flows with and without separation, which occur by variation of the aperture angle of a diffusor, are investigated. A probe for time and spatial measurements in turbulent flows was developed for estimating the pressure diffusion term in the equation of the k-epsilon turbulence model and for testing a gradient diffusion model for the transport of kinetic turbulent energy. For velocity measurement, a hot wire technique was chosen; for measuring the total pressure a sensor was mounted behind the hot wire. The conversion of the pressure signal into an electrical one was based on an electrical variometer and pressure proportional sensors, which allow the total pressure to be converted in a velocity and to be measured with a miniaturized hot wire; this process was chosen for simultaneous measurements of pressure and velocity oscillations. A miniaturized pressure chamber, in which a microphone and the pressure probe were parallel mounted, was used for estimating the frequency behavior of the pressure probe. An examination in the relaxation area of a 6 deg diffusor shows that the measuring instrumentation allows static pressure oscillations to be obtained and correlated with the velocity. ESA

SFOLDA: A SEMICONDUCTOR LDA FOR MEASUREMENTS IN COMPLEX FLOWS [SFOLDA: EIN HALBLEITER-LDA FUER MESSUNGEN IN KOMPLEXEN STROEMUNGEN]

M. Stieglmeier and C. Tropea *In* Tech. Univ. Berlin, Experimental Methods in Separated Flows 1991 p 44-51 In GERMAN (For primary document see N94-22852 06-34)

Avail: CASI HC A02/MF A01

The SFOLDA (Semiconductor Fiber Optic Laser Doppler Anemometer) is described and some application examples are presented. The system uses a temperature controlled diode laser head, a collimator lens system for beam diameter reduction, and an optical isolator based on the Faraday principle for suppression of optical feedback on the laser diode. A first system in which a Bragg cell simultaneously plays the role of beam separator and frequency shift unit allows weakly or strongly turbulent flows to be examined. In a second system with variable frequency shift, an optimal adaption of signal frequency to the signal processor is possible. In both systems, both beams are decoupled and focused in measure volume after beam amplification; the diffused light is detected above the emission lens and focused on a receptive fiber which drives the optical signal to an avalanche photodiode. The following examinations were carried out: boundary layer investigation in running trains; velocity measurements in fired combustion engine; and flow examination in a T shaped tube branch. The flexible, compact, and robust system is found to be particularly fitted to the study of flows with special boundary conditions. ESA

THE USE OF NEAR-WALL HOT-WIRE PROBES FOR TIME-RESOLVED SKIN-FRICTION MEASUREMENTS

Peter M. Wagner *In its* Experimental Methods in Separated Flows 1991 p 52-58 Submitted for publication (For primary document see N94-22852 06-34)

Avail: CASI HC A02/MF A01

The mean and fluctuating wall shear stress in turbulent air flows were measured. Hot wires were mounted at a fixed small distance from the wall and connected to a constant temperature anemometer and were operated at an overheat ratio of 35%. The mean skin friction was measured by a Preston tube. The pressure was determined using a digital micromanometer, directly read by a microcomputer. A calibration procedure was developed and the distortion of the probability density distribution due to the calibration curve nonlinearity was corrected. Experimental results in a flat plate boundary layer were obtained and compared to pulsed wire measurements. ESA

IMAGE PROCESSING FOR ACQUISITION OF FLUID REST TIME IN THE RUNNING OF AN ARTIFICIAL HEART VALVE [BILDVERARBEITUNG ZUR ERFASSUNG DER VERWEILZEITEN DES FLUIDS IM NACHLAUF EINER KUENSTLICHEN HERZKLAPPE]

K. Affeld, K. Schichl, A. Ziemann, and M. Freydefont (Ecole Polytechnique, Paris, France.) *In* Tech. Univ. Berlin, Experimental Methods in Separated Flows 1991 p 59-66 (For primary document see N94-22852 06-34)

Avail: CASI HC A02/MF A01

The blood flow separation which plays an important role in thrombosis formation is examined. A fluorescent coloring was homogeneously mixed with the water volume behind the valve in the aorta root for modeling blood platelets; a longitudinal circulating coloring cloud corresponds to a beginning of thrombosis while the water depicts the fresh blood. Coloring concentration was varied and these lightness changes were examined with a video system so that the gray values were quantified and their time dependence evaluated. The mean value was calculated and the concentration was established as an exponential function of time. The results show the thrombosis risk due to artificial heart valves. ESA

TURBULENT SEPARATED FLOWS ABOVE AN OBSTACLE IN AN OPEN CHANNEL [TURBULENTE ABGELOSTE STROMUNG UBER GRUNDSCHWELLEN IN EINEM OFFENEN GERINNE]

T. Loy, R. Friedrich, and U. Kertzscher *In* Tech. Univ. Berlin, Experimental Methods in Separated Flows 1991 p 67-76 (For primary document see N94-22852 06-34)

Avail: CASI HC A02/MF A01

The two dimensional, subcritical flow above several obstacles placed in an open rectangular channel is investigated. A resistance thermometer was used for temperature measurement and a laser Doppler anemometer for velocity measurement in the viscous sublayer. The separation and spreading behavior of the turbulence produced in the shear layer was experimentally estimated with dependence on obstacle geometry, cross flow, and water depth. Some comparative measurements in a two layer flow were carried out. Turbulence isolines which show that the turbulent transverse exchange increases with flatness of obstacles were obtained. The normed streamline function was deduced from measured profiles of mean velocity, through integration on the water depth; the calculations show that separation area length and height increase with obstacle flatness. A METHOD FOR RECOGNITION OF FREQUENCY CELLS IN A CYLINDER FLOW INFLUENCED BY WALL EFFECTS [EINE METHODE ZUR ERKENNUNG VON FREQUENZZELLEN IM VON RANDEFFEKTEN BEEINFLUSSTEN ZYLINDERNACHLAUF]

H. Eisenlohr, M. Koenig, and H. Eckelmann *In* Tech. Univ. Berlin, Experimental Methods in Separated Flows 1991 p 77-84 (For primary document see N94-22852 06-34)

Avail: CASI HC A02/MF A01

The flow around a cylinder too short to be considered as an infinite body is investigated with particular emphasis on the frequency of vortex separation from the cylinder. The time signal of a hot wire anemometer was evaluated in order to know the frequency as a function of time, in some areas where vortex branchings are observed and the spectrum shows two maxima at a node. A system with a voltage controlled oscillator, frequency modulation demodulators mounted on a chip and some phase comparators was used in order to obtain a phase locked loop. The Tritton spring, which is a discontinuity in the representation of Strouhal number as a function of Reynolds number and is considered as a boundary effect, is ascertained with the measurements. NONLOCAL MODELS IN CONTINUUM MECHANICS

N. L. Johnson and N. Phan-Thien (Sydney Univ., Australia.) 1993 15 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993

(Contract W-7405-eng-36)

(DE93-040146; LA-UR-93-3124; CONF-931121-21) Avail: CASI HC A03/MF A01

The recent appearance of nonlocal methods is examined in the light of traditional continuum mechanics. A comparison of nonlocal approaches in the fields of solid and fluid mechanics reveals that no consistent definition of a nonlocal theory has been used. A definition based on the violation of the principle of local action in continuum mechanics was suggested. From the consideration of the implications of a nonlocal theory based on this definition, it was concluded that constitutive relations with nonlocal terms can confuse the traditional separation of the roles between conservation laws and constitutive relations. The diversity of motivations for the nonlocal approaches are presented, resulting primarily from deficiencies in numerical solutions to practical problems. To illustrate these concepts, the history of nonlocal terms in the field of viscoelastic fluids is reviewed. A specific example of a viscoelastic constitutive relation that contains a stress diffusion term is applied to a simple shear flow and found not to be a physical description of any known fluid. Questions that should be asked of nonlocal approaches are listed. DOE

IMAGE ANALYSIS APPLICATIONS TO MIXING PHENOMENA AND TURBULENT DISPERSIONS Ph.D. Thesis [APPLICATIONS DE L'ANALYSE D'IMAGES A DES PHENOMENES DE MELANGE ET DE DISPERSION TURBULENTS]

Serge Simoens 1992 184 p In FRENCH Sponsored by Metraflu, Ecully, France Original contains color illustrations
(ECL-92-29; ETN-94-95168) Avail: CASI HC A09/MF A02

The purpose of the study is to demonstrate the importance of image analysis for flow visualization methods. Several classical flow visualization methods and image processing techniques are reviewed. Two image processing techniques are proposed. The first one is a qualitative analysis method applying a three dimensional reconstruction algorithm for complex shapes and laser tomography. The main difficulty is the nonreproducibility of three dimensional complex shapes. The solution adopted consists of harmonic analysis of two dimensional boundary layers. The following cases are used to test the method: coherent structures observed at the boundary layer transition zone and the reconstruction of gas plumes ejected into the atmosphere. A method developed for simultaneously measuring flow velocity and concentration fields is described. The results obtained by applying this technique to a nearly isotropic turbulent jet flow are discussed. ESA

LOCAL GRID REFINEMENT METHOD FOR THE EULER EQUATIONS Ph.D. Thesis

H. T. M. VanderMaarel 23 Feb. 1993 149 p See also PB92-202274
(PB93-223329) Avail: CASI HC A07/MF A02

The thesis considers the Euler equations of fluid dynamics for a perfect gas. Our main interest is the numerical approximation of solutions of the steady, two-dimensional Euler equations, by a solution-adaptive method, which uses local grid refinement (enrichment) and a multigrid method to solve the system of discrete equations. The Euler equations model the flow of a compressible, inviscid fluid, without taking into account the conduction of heat. Aerospace aerodynamics is an area of application interested in a physical model that neglects viscosity and heat conduction effects in the flow of a perfect gas. For an object moving through a gas, viscosity and heat conduction tend to play an important role only in the close vicinity of that object. Hence, in the 'outer' region (away from the object), a realistic description can often be made with the Euler equations. NTIS

AN EXPERIMENTAL STUDY OF THE FLOW FIELD SURROUNDING A SUBSONIC JET IN A CROSS FLOW M.S. Thesis

Robert Foster Dennis Jun. 1993 162 p
(Contract NCC2-731)
(NASA-CR-194770; NAS 1.26:194770) Avail: CASI HC A08/MF A02

An experimental investigation of the flow interaction of a 5.08 cm (2.00 in.) diameter round subsonic jet exhausting perpendicularly to a flat plate in a subsonic cross flow was conducted in the NASA Ames 7x1O ft. Wind Tunnel Number One. Flat plate surface pressures were measured at 400 locations in a 30.48 cm (12.0 in.) concentric circular array surrounding the jet exit. Results from these measurements are provided in tabular and graphical form for jet-to-crossflow velocity ratios ranging from 4 to 12, and for jet exit Mach numbers ranging from 0.50 to 0.93. Laser doppler velocimeter (LDV) three component velocity measurements were made in selected regions in the developed jet plume and near the flat plate surface, at a jet Mach number of 0.50 and jet-to-crossflow velocity ratios of 6 and 8. The results of both pressure and LDV measurements are compared with the results of previous experiments. In addition, pictures of the jet plume shape at jet velocity ratios ranging from 4 to 12 were obtained using schleiren photography. The LDV measurements are consistent with previous work, but more extensive measurements will be necessary to provide a detailed picture of the flow field. The surface pressure results compare closely with previous work and provide a useful characterization of jet induced surface pressures. The results demonstrate the primary influence of jet velocity ratio and the secondary influence of jet Mach number in determining such surface pressures. Author (revised)

PROBE SHAPES THAT MEASURE TIME-AVERAGED STREAMWISE MOMENTUM AND CROSS-STREAM TURBULENCE INTENSITY Patent

Vernon J. Rossow, inventor (to NASA) 7 Sep. 1993 21 p Filed 21 Feb. 1991
(NASA-Case-ARC-11934-1; US-Patent-5,241,866;
US-Patent-Appl-SN-660473; US-Patent-Class-73-861.66;
US-Patent-Class-73-170.14; US-Patent-Class-73-147;
US-Patent-Class-73-180; Int-Patent-Class-G01F-1/46) Avail: US Patent and Trademark Office

A method and apparatus for directly measuring the time-averaged streamwise momentum in a turbulent stream use a probe which has total head response which varies as the cosine-squared of the angle of incidence. The probe has a nose with a slight indentation on its front face for providing the desired response. The method of making the probe incorporates unique design features. Another probe may be positioned in a side-by-side relationship to the first probe to provide a direct measurement of the total pressure. The difference between the two pressures yields the sum of the squares of the cross-stream components of the turbulence level. Official Gazette of the U.S. Patent and Trademark Office

FLAMES IN DUSTY MIXTURES: THEIR STRUCTURE AND STABILITY Final Report

J. Buckmaster (Illinois Univ., Urbana.) and T. Jackson Nov. 1993 24 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191567; NAS 1.26:191567; ICASE-93-86) Avail: CASI HC A03/MF A01

The structure and stability of flames in dusty mixtures is investigated. The presence of the dust leads to significant transport of energy by radiation and the fundamental goal of the analysis is to explore to what extent this displaces the classical non-hydrodynamical stability boundaries of the plane degradation. An approximate description of the radiative transport permits analysis for arbitrary values of both the planck length and the Boltzman number. It is shown that the pulsating/traveling-wave instability usually associated with values of Lewis number (L(sub e)) bigger than 1 is stongly enhanced by the presence of radiation and can be present even if L(sub e) is less than 1. On the other hand radiation tends to supress the cellular instability normally associated with values of L(sub e) less than 1. The latter is consisitent with preliminary experimental observations of Abbud-Madrid and Ronney. Author (revised)

TWO-DIMENSIONAL NAVIER-STOKES COMPUTATIONS OF SUBSONIC AND SUPERSONIC FLOWS THROUGH TURBINE CASCADES

H. Pan 1993 38 p
(PB93-226223; ISBN-951-22-1482-2) Avail: CASI HC A03/MF A01

The report describes the computation of 2-D viscous flows in turbine cascades. The program is a 2-D FINFLO code developed at the Laboratory of Aerodynamics, Helsinki University of Technology. The original code was developed for external flows and dimensionless variables are employed in the computation. The external version of the code was modified to be suitable for internal flows and dimensional input-output quantities was used.

A subsonic 2-D axial turbine cascade flow case and a supersonic 2-D radial turbine cascade flow case was calculated. The results from the first case are compared with the results of the experiment conducted by NASA. NTIS

POISs3: A 3D POISSON SMOOTHER OF STRUCTURED GRIDS

R. Lehtimaeki 1993 50 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-226231; SER-B-93-42) Avail: CASI HC A03

Flow solvers based on solving Navier-Stokes or Euler equations generally need a computational grid to represent the domain of the flow. A structured computational grid can be efficiently produced by algebraic methods like transfinite interpolation. Unfortunately, algebraic methods propagate all kinds of unsmoothness of the boundary into the field. Unsmoothness of the grid, in turn, can result in inaccuracy in the flow solver. In the present work a 3D elliptic grid smoother was developed. The smoother is based on solving three Poisson equations, one for each curvilinear direction. The Poisson equations formed in the physical region are first transformed to the computational (rectilinear) region. The resulting equations form a system of three coupled elliptic quasi-linear partial differential equations in the computational domain. A short review of the Poisson method is presented. The regularity of a grid cell is studied and a skewness value is developed. NTIS

INTERFEROMETRY IN RAREFIED GAS FLOWS

G. Smeets 10 Apr. 1992 14 p Presented at the Advance Research Workshop on New Trends in Instrumentation for Hypersonic Research, Le Fauga, France, 27 Apr. - 1 May 1992
(ISL-CO-207/92; ETN-94-95123) Avail: CASI HC A03/MF A01

A survey of optical interferometry using a Wollaston prism differential interferometer is given. With a number of selected examples, its potential, especially in the field of low density flow diagnostics, is demonstrated. Differential interferometry with spark light sources is treated and is shown to be a very effective means for high sensitive flow visualization. The laser differential interferometer originating from a combination of the differential interferometer with collimated light beams from a continuous wave laser is described. Of special interest for applications to rarefied flows is its capability of resolving optical path changes down to 0.00001 of the light wavelength. This is three orders of magnitude beyond the resolution limit of classical interferometry based on fringe shift analysis. ESA

LIQUID OSCILLATIONS IN A SPHERICAL SYSTEM WITH SLIDING EDGES BOUNDARY BY TWO CONICAL SOLID SURFACES IN ZERO-GRAVITY

Helmut F. Bauer 1992 30 p
(LRT-WE-9-FB-5-1992; ETN-94-95090) Avail: CASI HC A03/MF A01

The natural frequencies and damped natural frequencies of an annular spherical liquid system bounded by two conical solid surfaces were determined by considering three cases for the contact line motion. These were the freely slipping contact line, the 'sliding', and the anchored contact line. The analytical results are applied to a semispherical drop, where it was found that the natural frequencies range from those for free slipping to those for anchored edges. The system of viscous liquid also exhibits a domain where only aperiodic motion is possible. ESA

FORCED VIBRATIONS OF A NON-VISCOUS DROP

W. Moehring and R. Ravindran (Indian Inst. of Science, Bangalore.) Oct. 1992 66 p Sponsored by Alexander von Humboldt Stiftung
(MPIS-24/1992; ETN-94-95104) Avail: CASI HC A04/MF A01

Using a variational principle with the Lagrangian dictated by the pressure, the nonlinear axisymmetric oscillations of a drop in an incompressible inviscid fluid are studied. The drop shape and periodicity of oscillation of the unperturbed drop are investigated. The variational principle is modified to account for an external enforced oscillation. The motion of the drop under the effect of external oscillations with various periods is studied using Poincare maps, Melnikov method, and winding numbers. Of special interest are 'mode locked' states, where the drop oscillates with the external frequency. ESA

ASYMPTOTIC ANALYSIS: WORKING NOTE NO. 3, BOUNDARY LAYERS

M. Garbey (Lyon-1 Univ., Villeurbanne, France.) and H. G. Kaper Sep. 1993 20 p
(Contract W-31-109-eng-38)
(DE94-002299; ANL/MCS-TM-181) Avail: CASI HC A03/MF A01

In this chapter the authors discuss the asymptotic approximation of functions that display boundary layer behavior. The purpose here is to introduce the basic concepts underlying the phenomenon, to illustrate its importance, and to describe some of the fundamental tools available for its analysis. To achieve their purpose in the clearest way possible, the authors will work with functions that are assumed to be given explicitly - that is, functions f : (0,epsilon(sub 0)) yields X whose expressions are known, at least in principle. Only in the following chapter will they begin the study of functions that are given implicitly as solutions of boundary value problems - the real stuff of which singular perturbation theory is made. Boundary-layer behavior is associated with asymptotic expansions that are regular 'almost everywhere' - that is, expansions that are regular on every compact subset of the domain of definition, but not near the boundary. These regular asymptotic expansions can be continued in a certain sense all the way up to the boundary, but a separate analysis is still necessary in the boundary layer. The boundary layer analysis is purely local and aims at constructing local approximations in the neighborhood of each point of the singular part of the boundary. The problem of finding an asymptotic approximation is thus reduced to matching the various local approximations to the existing regular expansion valid in the interior of the domain. The authors are thinking, for example, of fluid flow (viscosity), combustion (Lewis number), and superconductivity (Ginzburg-Landau parameter) problems. Their solution may remain smooth over a wide range of parameter values, but as the parameters approach critical values, complicated patterns may emerge. DOE

A METHOD TO SIMULATE VISCOUS DIFFUSION OF VORTICITY BY CONVECTIVE TRANSPORT OF VORTICES AT A NON-SOLENOIDAL VELOCITY

S. N. Kempka and J. H. Strickland Aug. 1993 30 p
(Contract DE-AC04-94AL-85000)
(DE94-001777; SAND-93-1763) Avail: CASI HC A03/MF A01

A numerical method to simulate viscous diffusion of vorticity using vortex blobs (i.e., without a grid) is presented. The method consists of casting the effects of viscous diffusion into an effective 'diffusion velocity' at which vortex blobs convect. The diffusion velocity was proposed previously by Ogami and Akamatsu, but they did not consider the effects of the divergence of the diffusion velocity. In fact, the diffusion velocity is highly non-solenoidal, which significantly affects the area over which a vortex blob diffuses. A formulation is presented that relates the area expansion to the diffusion velocity divergence. By taking into account the area expansion, more accurate simulations of diffusion are obtained, as demonstrated by a comparison of numerical and analytical diffusion solutions. Results from simulations show that vortex areas expand significantly in regions of large vorticity gradients. As a result of the area expansion, adjacent vortices remain overlapped, thereby maintaining smooth solution fields. The non-solenoidal diffusion velocity method is easily implemented in vortex blob algorithms, thus facilitating the development of vortex methods to simulate flows with finite Reynolds numbers. DOE

A REPRESENTATION FOR THE TURBULENT MASS FLUX CONTRIBUTION TO REYNOLDS-STRESS AND TWO-EQUATION CLOSURES FOR COMPRESSIBLE TURBULENCE Final Report
J. R. Ristorcelli Nov. 1993 24 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191569; NAS 1.26:191569; ICASE-93-88) Avail: CASI HC A03/MF A01

The turbulent mass flux, or equivalently the fluctuating Favre velocity mean, appears in the first and second moment equations of compressible kappa-epsilon and Reynolds stress closures. Mathematically it is the difference between the unweighted and density-weighted averages of the velocity field and is therefore a measure of the effects of compressibility through variations in density. It appears to be fundamental to an inhomogeneous compressible turbulence, in which it characterizes the effects of the mean density gradients, in the same way the anisotropy tensor characterizes the effects of the mean velocity gradients. An evolution equation for the turbulent mass flux is derived. A truncation of this equation produces an algebraic expression for the mass flux. The mass flux is found to be proportional to the mean density gradients with a tensor eddy-viscosity that depends on both the mean deformation and the Reynolds stresses. The model is tested in a wall bounded DNS at Mach 4.5 with notable results. Author (revised)

PROBE SYSTEMS FOR MEASURING STATIC PRESSURE AND TURBULENCE INTENSITY IN FLUID STREAMS Patent
Vernon J. Rossow, inventor (to NASA) 10 Aug. 1993 19 p Filed 24 Apr. 1991
(NASA-Case-ARC-11935-1; US-Patent-5,233,865; US-Patent-Appl-SN-690440; US-Patent-Class-73-147; US-Patent-Class-73-861.65; Int-Patent-Class-G01F-1/46; Int-Patent-Class-G01P-5/165) Avail: US Patent and Trademark Office

A method and an apparatus for measuring time-averaged static or ambient pressure and turbulence intensity in a turbulent stream are discussed. The procedure involves placing a plurality of probes in the stream. Each probe responds in a different manner to characteristics of the fluid stream, preferably as a result of having varying cross sections. The responses from the probes are used to eliminate unwanted components in the measured quantities for accurate determination of selected characteristics.

EXPERIMENTAL INVESTIGATION OF GENERIC THREE-DIMENSIONAL SIDEWALL-COMPRESSION SCRAMJET INLETS AT MACH 6 IN TETRAFLUOROMETHANE
Scott D. Holland Dec. 1993 47 p
(RTOP 506-40-41-02)
(NASA-TM-4497; L-17133; NAS 1.15:4497) Avail: CASI HC A03/MF A01

Three-dimensional sidewall-compression scramjet inlets with leading-edge sweeps of 30 deg and 70 deg were tested in the Langley Hypersonic CF4 Tunnel at Mach 6 and with a ratio of specific heats of 1.2. The parametric effects of leading-edge sweep, cowl position, contraction ratio, and Reynolds number were investigated. The models were instrumented with 42 static pressure orifices that were distributed on the sidewalls, base plate, and cowl. Schlieren movies were made of each test for flow visualization of the effects of the internal flow spillage on the external flow field. To obtain an approximate characterization of the flow field, a modification to two-dimensional, inviscid, oblique shock theory was derived to accommodate the three-dimensional effects of leading-edge sweep. This theory qualitatively predicted the reflected shock structure (i.e., sidewall impingement locations) and the observed increase in spillage with increasing leading-edge sweep. The primary effect of moving the cowl forward was capturing the flow that would have otherwise spilled out ahead of the cowl. Increasing the contraction ratio increases the number of internal shock reflections and hence incrementally increases the sidewall pressure distribution. Significant Reynolds number effects were noted over a small range of Reynolds number. Author (revised)

Experiments are described on shock propagation through 2-D aligned and staggered baffle systems. Flow visualization was provided by shadow and schlieren photography, which was recorded by the Cranz-Schardin camera. Also, single-frame, infinite-fringe, color interferograms were used. Intuition suggests that this is a rather simple 2-D shock diffraction problem. However, flow visualization reveals that the flow rapidly evolved into a complex 3-D turbulent mixing problem. Mushroom-shaped mixing regions blocked the flow into the next baffle orifice. Thus energy was transferred from the directed kinetic energy (induced by the shock) to the rotational energy of turbulent mixing and then dissipated by molecular effects. These processes dramatically dissipate the strength of the shock wave. The experiments provide an excellent test case that could be used to assess the accuracy of computer code calculations of such problems. DOE

THE USE OF TRANSITION REGION CHARACTERISTICS TO IMPROVE THE NUMERICAL SIMULATION OF HEAT TRANSFER IN BYPASS TRANSITIONAL FLOWS
Frederick F. Simon Dec. 1993 19 p Prepared for presentation at the 5th International Symposium on Transport Phenomena and Dynamics of Rotating Machinery, Kaanapali, Maui, HI, 8-11 May 1994; sponsored by the Pacific Center of Thermal-Fluids Engineering
(RTOP 505-62-52)
(NASA-TM-106445; E-8290; NAS 1.15:106445) Avail: CASI HC A03/MF A01

A method is presented for improving the numerical prediction of bypass transition heat transfer on a flat plate in a high-disturbance environment with zero or favorable pressure gradient. The method utilizes low Reynolds number k-epsilon turbulence models in combination with the characteristic parameters of the transition region. The parameters representing the characteristics of the transition region used are the intermittency, transition length and turbulent spot properties. An analysis is made of the transition length in terms of turbulent spot variables. The nondimensional spot formation rate, required for the prediction of the transition length, is shown by the analysis to be a function of the spot spreading angle, the dimensionless spot velocity ratio and the dimensionless spot area ratio. The intermittency form of the k-epsilon equations were derived from conditionally averaged equations which have been shown to be an improvement over global-time-averaged equations for the numerical calculation of the transition region. The numerical predictions are in general good agreement with the experimental data and indicate the potential use of the method in accelerating flows. Turbulence models of the k-epsilon type are known to underpredict the transition length. The present work demonstrates how incorporating transition region characteristics improves the ability of two-equation turbulence models to simulate bypass transition for flat plates with potential application to turbine vanes and blades. THE FIFTH ANNUAL THERMAL AND FLUIDS ANALYSIS WORKSHOP
Nov. 1993 533 p Workshop held in Brook Park, OH, 16-20 Aug. 1993; cosponsored by Ohio Aerospace Inst. Original contains color illustrations
(NASA-CP-10122; E-8094; NAS 1.55:10122) Avail: CASI HC A23/MF A04; 5 functional color pages

The Fifth Annual Thermal and Fluids Analysis Workshop was held at the Ohio Aerospace Institute, Brook Park, Ohio, cosponsored by NASA Lewis Research Center and the Ohio Aerospace Institute, 16-20 Aug. 1993. The workshop consisted of classes, vendor demonstrations, and paper sessions. The classes and vendor demonstrations provided participants with the information on widely used tools for thermal and fluid analysis. The paper sessions provided a forum for the exchange of information and ideas among thermal and fluids analysts. Paper topics included advances and uses of established thermal and fluids computer codes (such as SINDA and TRASYS) as well as unique modeling techniques and applications. For individual titles, see N94-23635 through N94-23672.

ADVANCED X RAY ASTROPHYSICS FACILITY-IMAGING (AXAF-I) THERMAL ANALYSES USING INTEGRATED THERMAL ANALYSIS SYSTEM (ITAS) PROGRAM
Benny Ghaffarian (Sverdrup Technology, Inc., Huntsville, AL.) and Ramona Cummings *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 3-12 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

The complex geometry and stringent thermal requirements associated with the Advanced X-ray Astrophysics Facility - Imaging (AXAF-I) necessitate a detailed and accurate thermal analysis of the proposed system. A brief description of said geometry and thermal requirements is included. Among the tools considered for the aforementioned analysis is a PC-compatible version of the Integrated Thermal Analysis System (ITAS). Several bench-mark studies were performed to evaluate the capabilities of ITAS and to compare the corresponding results with those obtained using TRASYS and SINDA. Comparative studies were conducted for a typical Space Station module. Four models were developed using various combinations of the available software packages (i.e. ITAS, SINDA, and TRASYS). Orbital heating and heat transfer calculations were performed to determine the temperature distributions along the surfaces of this module. A comparison of the temperature distributions obtained for each of the four cases is presented. Results of this investigation were used to verify the different ITAS modules including those used for model generation, steady state and transient orbital heating analyses, radiative and convective heat flow analyses, and SINDA/TRASYS model translation. The results suggest that ITAS is well suited to subsequent analyses of the AXAF-I. Author (revised)

AN ENGINEERING CODE TO ANALYZE HYPERSONIC THERMAL MANAGEMENT SYSTEMS
Valerie J. VanGriethuysen and Clark E. Wallace (Science Applications International Corp., Torrance, CA.) *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 13-26 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

Thermal loads on current and future aircraft are increasing and as a result are stressing the energy collection, control, and dissipation capabilities of current thermal management systems and technology. The thermal loads for hypersonic vehicles will be no exception. In fact, with their projected high heat loads and fluxes, hypersonic vehicles are a prime example of systems that will require thermal management systems (TMS) that have been optimized and integrated with the entire vehicle to the maximum extent possible during the initial design stages. This will not only be to meet operational requirements, but also to fulfill weight and performance constraints in order for the vehicle to takeoff and complete its mission successfully. To meet this challenge, the TMS can no longer be two or more entirely independent systems, nor can thermal management be an after thought in the design process, the typical pervasive approach in the past. Instead, a TMS that was integrated throughout the entire vehicle and subsequently optimized will be required. To accomplish this, a method that iteratively optimizes the TMS throughout the vehicle will not only be highly desirable, but advantageous in order to reduce the manhours normally required to conduct the necessary tradeoff studies and comparisons. A thermal management engineering computer code that is under development and being managed at Wright Laboratory, Wright-Patterson AFB, is discussed. The primary goal of the code is to aid in the development of a hypersonic vehicle TMS that has been optimized and integrated on a total vehicle basis. Author (revised)

UNCERTAINTY ANALYSIS OF DIFFUSE-GRAY RADIATION ENCLOSURE PROBLEMS: A HYPERSENSITIVE CASE STUDY
Robert P. Taylor, Rogelio Luck, B. K. Hodge, and W. Glenn Steele *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis

Workshop Nov. 1993 p 27-40 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

An uncertainty analysis of diffuse-gray enclosure problems is presented. The genesis was a diffuse-gray enclosure problem which proved to be hypersensitive to the specification of view factors. This genesis is discussed in some detail. The uncertainty analysis is presented for the general diffuse-gray enclosure problem and applied to the hypersensitive case study. It was found that the hypersensitivity could be greatly reduced by enforcing both closure and reciprocity for the view factors. The effects of uncertainties in the surface emissivities and temperatures are also investigated. Author

Avail: CASI HC A02/MF A04; 5 functional color pages

As the workstation and personal computer become more popular than a centralized mainframe to perform thermal analysis, the methods for space vehicle thermal analysis will change. Already, many thermal analysis codes are now available for workstations, which were not in existence just five years ago. As these changes occur, some organizations will adopt the new codes and analysis techniques, while others will not. This might lead to misunderstandings between thermal shops in different organizations. If thermal analysts make an effort to understand the major differences between the new and old methods, a smoother transition to a more efficient and more versatile thermal analysis environment will be realized. ACCURACY CONTROL IN MONTE CARLO RADIATIVE CALCULATIONS
P. Planas Almazan *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 47-62 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The general accuracy law that rules the Monte Carlo, ray-tracing algorithms used commonly for the calculation of the radiative entities in the thermal analysis of spacecraft are presented. These entities involve transfer of radiative energy either from a single source to a target (e.g., the configuration factors). or from several sources to a target (e.g., the absorbed heat fluxes). In fact, the former is just a particular case of the latter. The accuracy model is later applied to the calculation of some specific radiative entities. Furthermore, some issues related to the implementation of such a model in a software tool are discussed. Although only the relative error is considered through the discussion, similar results can be derived for the absolute error. Author (revised)

A thermal control system was designed for the Space Station Freedom (SSF) sensor/electronics box (SSTACK). Multi-layer insulation and heaters are used to maintain the temperatures of the critical components within their operating and survival temperature limits. Detailed and simplified SSTACK thermal models were developed and temperatures were calculated for worst-case orbital conditions. A comparison between the two models showed very good agreement. Temperature predictions were also compared to measured temperatures from a thermal-vacuum test. Author (revised)

Avail: CASI HC A03/MF A04; 5 functional color pages

The status of research on the transient behavior of finned coil cross-flow heat exchangers using single phase fluids is reviewed. Applications with available analytical or numerical solutions are discussed. Investigation of water-to-air type cross-flow finned tube heat exchangers is examined through the use of simplified governing equations and an up-wind finite difference scheme. The degenerate case of zero air-side capacitance rate is compared with available exact solution. Generalization of the numerical model is discussed for application to multi-row multi-circuit heat exchangers. Author (revised)

SOLUTION OF MIXED CONVECTION HEAT TRANSFER FROM ISOTHERMAL IN-LINE FINS
Amir Khalilollahi *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 127-136 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

Transient and steady state combined natural and forced convective flows over two in-line finite thickness fins (louvers) in a vertical channel are numerically solved using two methods. The first method of solution is based on the 'Simple Arbitrary Lagrangian Eulerian' (SALE) technique which incorporates mainly two computational phases: (1) a Lagrangian phase in which the velocity field is updated by the effects of all forces, and (2) an Eulerian phase that executes all advective fluxes of mass, momentum and energy. The second method of solution uses the finite element code entitled FIDAP. In the first part, comparison of the results by FIDAP, SALE, and available experimental work were done and discussed for steady state forced convection over louvered fins. Good agreements were deduced between the three sets of results especially for the flow over a single fin. In the second part and in the absence of experimental literature, the numerical predictions were extended to the transient transports and to the opposing flow where pressure drop is reversed. Results are presented and discussed for heat transfer and pressure drop in assisting and opposing mixed convection flows. Author (revised)

A DIRECT APPROACH TO FINDING UNKNOWN BOUNDARY CONDITIONS IN STEADY HEAT CONDUCTION
Thomas J. Martin and George S. Dulikravich *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 137-149 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The capability of the boundary element method (BEM) in determining thermal boundary conditions on surfaces of a conducting solid where such quantities are unknown was demonstrated. The method uses a non-iterative direct approach in solving what is usually called the inverse heat conduction problem (IHCP). Given any over-specified thermal boundary conditions such as a combination of temperature and heat flux on a surface where such data is readily available, the algorithm computes the temperature field within the object and any unknown thermal boundary conditions on surfaces where thermal boundary values are unavailable. A two-dimensional, steady-state BEM program was developed and was tested on several simple geometries where the analytic solution was known. Results obtained with the BEM were in excellent agreement with the analytic values. The algorithm is highly flexible in treating complex geometries, mixed thermal boundary conditions, and temperature-dependent material properties and is presently being extended to three-dimensional and unsteady heat conduction problems. The accuracy and reliability of this technique was very good but tended to deteriorate when the known surface conditions were only slightly over-specified and far from the inaccessible surface. SECOND LAW ANALYSIS OF A CONVENTIONAL STEAM POWER PLANT c77
Geng Liu, Robert H. Turner, and Yunus A. Cengel *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 151-166 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

A numerical investigation of exergy destroyed by operation of a conventional steam power plant is computed via an exergy cascade. An order of magnitude analysis shows that exergy destruction is dominated by combustion and heat transfer across temperature differences inside the boiler, and conversion of energy entering the turbine/generator sets from thermal to electrical. Combustion and heat transfer inside the boiler accounts for 53.83 percent of the total exergy destruction. Converting thermal energy into electrical energy is responsible for 41.34 percent of the total exergy destruction. Heat transfer across the condenser accounts for 2.89 percent of the total exergy destruction. Fluid flow with friction is responsible for 0.50 percent of the total exergy destruction. The boiler feed pump turbine accounts for 0.25 percent of the total exergy destruction. Fluid flow mixing is responsible for 0.23 percent of the total exergy destruction. Other equipment including gland steam condenser, drain cooler, deaerator and heat exchangers are, in the aggregate, responsible for less than one percent of the total exergy destruction. An energy analysis is also given for comparison of exergy cascade to energy cascade. Efficiencies based on both the first law and second law of thermodynamics are calculated for a number of components and for the plant. The results show that high first law efficiency does not mean high second law efficiency. Therefore, the second law analysis has been proven to be a more powerful tool in pinpointing real losses. The procedure used to determine total exergy destruction and second law efficiency can be used in a conceptual design and parametric study to evaluate the performance of other steam power plants and other thermal systems. SOME USEFUL INNOVATIONS WITH TRASYS AND SINDA-85 c61
Ruth M. Amundsen *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 169-184 Original contains color illustrations (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

Several innovative methods were used to allow more efficient and accurate thermal analysis using SINDA-85 and TRASYS, including model integration and reduction, planetary surface calculations, and model animation. Integration with other modeling and analysis codes allows an analyst to import a geometry from a solid modeling or computer-aided design (CAD) software package, rather than building the geometry 'by hand.' This is more efficient as well as potentially more accurate. However, the use of solid modeling software often generates large analytical models. The problem of reducing large models was elegantly solved using the response of the transient derivative to a forcing step function. The thermal analysis of a lunar rover implemented two unusual features of the TRASYS/SINDA system. A little-known TRASYS routine SURFP calculates the solar heating of a rover on the lunar surface for several different rover positions and orientations. This is used not only to determine the rover temperatures, but also to automatically determine the power generated by the solar arrays. The animation of transient thermal results is an effective tool, especially in a vivid case such as the 14-day progress of the sun over the lunar rover. An animated color map on the solid model displays the progression of temperatures. Author (revised)

ANALYSIS OF HIGH VACUUM SYSTEMS USING SINDA'85 c61
R. A. Spivey, S. E. Clanton, and J. D. Moore *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 185-204 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The theory, algorithms, and test data correlation analysis of a math model developed to predict performance of the Space Station Freedom Vacuum Exhaust System are presented. The theory used to predict the flow characteristics of viscous, transition, and molecular flow is presented in detail. Development of user subroutines which predict the flow characteristics in conjunction with the SINDA'85/FLUINT analysis software are discussed. The resistance-capacitance network approach with application to vacuum system analysis is demonstrated and results from the model are correlated with test data. The model was developed to predict the performance of the Space Station Freedom Vacuum Exhaust System. However, the unique use of the user subroutines developed in this model and written into the SINDA'85/FLUINT thermal analysis model provides a powerful tool that can be used to predict the transient performance of vacuum systems and gas flow in tubes of virtually any geometry. This can be accomplished using a resistance-capacitance (R-C) method very similar to the methods used to perform thermal analyses. Author (revised)

FEATURES OF A SINDA/FLUINT MODEL OF A LIQUID OXYGEN SUPPLY LINE
Boris G. Simmonds *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 205-222 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The modeling features used in a steady-state heat transfer problem using SINDA/FLUINT are described. The problem modeled is a 125 feet long, 3 inch diameter pipe, filled with liquid oxygen flow driven by a given pressure gradient. The pipe is fully insulated in five sections. Three sections of 1 inch thick spray-on foam and two sections of vacuum jacket. The model evaluates friction, turns losses and convection heat transfer between the fluid and the pipe wall. There is conduction through the foam insulation with temperature dependent thermal conductivity. The vacuum space is modeled with radiation and gas molecular conduction, if present, in the annular gap. Heat is transferred between the outer surface and surrounding ambient by natural convection and radiation; and, by axial conduction along the pipe and through the vacuum jacket spacers and welded seal flanges. The model makes extensive use of SINDA/FLUINT basic capabilities such as the GEN option for nodes and conductors (to generate groups of nodes or conductors), the SIV option (to generate single, temperature varying conductors), the SIM option (for multiple, temperature varying conductors) and the M HX macros for fluids (to generate strings of lumps, paths, and ties representing a diabatic duct). It calls subroutine CONTRN (returns the relative location in the G-array of a network conductor, given

an actual conductor number) enabling an extensive manipulation of conductor (calculates an assignment of their values) with DO loops. Models like this illustrate to the new and even to the old SINDA/FLUINT user, features of the program that are not so obvious or known, and that are extremely handy when trying to take advantage of both, the automation of the DATA headers and make surgical modifications to specific parameters of the thermal or fluid elements in the OPERATIONS portion of the model.

CONVECTION EQUATION MODELING: A NON-ITERATIVE DIRECT MATRIX SOLUTION ALGORITHM FOR USE WITH SINDA c61
Dean S. Schrage *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 237-251 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The determination of the boundary conditions for a component-level analysis, applying discrete finite element and finite difference modeling techniques often requires an analysis of complex coupled phenomenon that cannot be described algebraically. For example, an analysis of the temperature field of a coldplate surface with an integral fluid loop requires a solution to the parabolic heat equation and also requires the boundary conditions that describe the local fluid temperature. However, the local fluid temperature is described by a convection equation that can only be solved with the knowledge of the locally-coupled coldplate temperatures. Generally speaking, it is not computationally efficient, and sometimes, not even possible to perform a direct, coupled phenomenon analysis of the component-level and boundary condition models within a single analysis code. An alternative is to perform a disjoint analysis, but transmit the necessary information between models during the simulation to provide an indirect coupling. For this approach to be effective, the component-level model retains full detail while the boundary condition model is simplified to provide a fast, first-order prediction of the phenomenon in question. Specifically for the present study, the coldplate structure is analyzed with a discrete, numerical model (SINDA) while the fluid loop convection equation is analyzed with a discrete, analytical model (direct matrix solution). This indirect coupling allows a satisfactory prediction of the boundary condition, while not subjugating the overall computational efficiency of the component-level analysis. In the present study a discussion of the complete analysis of the derivation and direct matrix solution algorithm of the convection equation is presented. Discretization is analyzed and discussed to extend of solution accuracy, stability and computation speed. Case studies considering a pulsed and harmonic inlet disturbance to the fluid loop are analyzed to assist in the discussion of numerical dissipation and accuracy. In addition, the issues of code melding or integration with standard class solvers such as SINDA are discussed to advise the user of the potential problems to be encountered. Author

SIMULATION OF UNSTEADY FLOWS THROUGH STATOR AND ROTOR BLADES OF A GAS TURBINE USING THE CHIMERA METHOD
S. Nakamura and J. N. Scott *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 255-267 Sponsored in part by Ohio Aerospace Inst. (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

A two-dimensional model to solve compressible Navier-Stokes equations for the flow through stator and rotor blades of a turbine is developed. The flow domains for the stator and rotor blades are coupled by the Chimera method that makes grid generation easy and enhances accuracy because the area of the grid that have high turning of grid lines or high skewness can be eliminated from the computational domain after the grids are generated. The results of flow computations show various important features of unsteady flows including the acoustic waves interacting with boundary layers, Karman vortex shedding from the trailing edge of the stator blades, pulsating incoming flow to a rotor blade from passing stator blades, and flow separation from both suction and pressure sides of the rotor blades.

Avail: CASI HC A03/MF A04; 5 functional color pages

The relationship between actual and predicted re-entry maximum dynamic pressure is characterized using a probability density function and a cumulative distribution function derived from sounding rocket flight data. This paper explores the properties of this distribution and demonstrates applications of this data with observed sounding rocket re-entry body damage characteristics to assess probabilities of sustaining various levels of heating damage. The results from this paper effectively bridge the gap existing in sounding rocket reentry analysis between the known damage level/flight environment relationships and the predicted flight environment. Free molecular heating (FMH) is caused by the transfer of energy during collisions between the upper atmosphere molecules and a space vehicle. The dispersed free molecular heating on a surface is an important constraint for space vehicle thermal analyses since it can be a significant source of heating. To reduce FMH to a spacecraft, the parking orbit is often designed to a higher altitude at the expense of payload capability. Dispersed FMH is a function of both space vehicle velocity and atmospheric density, however, the space vehicle velocity variations are insignificant when compared to the atmospheric density variations. The density of the upper atmosphere molecules is a function of altitude, but also varies with other environmental factors, such as solar activity, geomagnetic activity, location, and time. A method has been developed to predict three sigma maximum dispersed density for up to 15 years into the future. This method uses a state-of-the-art atmospheric density code, MSIS 86, along with 50 years of solar data, NASA and NOAA solar activity predictions for the next 15 years, and an Aerospace Corporation correlation to account for density code inaccuracies to generate dispersed maximum density ratios denoted as 'K-factors'. The calculated K-factors can be used on a mission unique basis to calculate dispersed density, and hence dispersed free molecular heating rates. These more accurate K-factors can allow lower parking orbit altitudes, resulting in increased payload capability. Author

MIXING AND UNMIXEDNESS IN PLASMA JETS 1: NEAR-FIELD ANALYSIS c75
Olusegun J. Ilegbusi *In* NASA. Lewis Research Center, The Fifth Annual

Thermal and Fluids Analysis Workshop Nov. 1993 p 307-328 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The flow characteristics in the near-field of a plasma jet are simulated with a two-fluid model. This model accounts for both gradient-diffusion mixing and uni-directional sifting motion resulting from pressure-gradient-body-force imbalance. This latter mechanism is believed to be responsible for the umixedness observed in plasma jets. The unmixedness is considered to be essentially a Rayleigh-Taylor kind instability. Transport equations are solved for the individual plasma and ambient gas velocities, temperatures and volume fractions. Empirical relations are employed for the interface transfers of mass, momentum and heat. The empirical coefficients are first established by comparison of predictions with available experimental data for shear flows. The model is then applied to an Argon plasma jet ejecting into stagnant air. The predicted results show the significant build-up of unmixed air within the plasma gas, even relatively far downstream of the torch. By adjusting the inlet condition, the model adequately reproduces the experimental data. Author

SUPERSONIC MINIMUM LENGTH NOZZLE DESIGN FOR DENSE GASES **c02**
Andrew C. Aldo and Brian M. Argrow *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 329-341 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

Recently, dense gases have been investigated for many engineering applications such as for turbomachinery and wind tunnels. Supersonic nozzle design for these gases is complicated by their nonclassical behavior in the transonic flow regime. In this paper a method of characteristics (MOC) is developed for two-dimensional (planar) and, primarily, axisymmetric flow of a van der Waals gas. Using a straight aortic line assumption, a centered expansion is used to generate an inviscid wall contour of minimum length. The van der Waals results are compared to previous perfect gas results to show the real gas effects on the flow properties and inviscid wall contours. Author

EXPERIMENTAL AND ANALYTICAL STUDY OF CRYOGENIC PROPELLANT BOILOFF TO DEVELOP AND VERIFY ALTERNATE PRESSURIZATION CONCEPTS FOR SPACE SHUTTLE EXTERNAL TANK USING A SCALED DOWN TANK **c28**
K. M. Akyuzlu, S. Jones (Martin Marietta Corp., New Orleans, LA.), and T. Meredith (Martin Marietta Corp., New Orleans, LA.) *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 343-358 Sponsored in part by Martin Marietta Corp. (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

Self pressurization by propellant boiloff is experimentally studied as an alternate pressurization concept for the Space Shuttle external tank (ET). The experimental setup used in the study is an open flow system which is composed of a variable area test tank and a recovery tank. The vacuum jacketed test tank is geometrically similar to the external LOx tank for the Space Shuttle. It is equipped with instrumentation to measure the temperature and pressure histories within the liquid and vapor, and viewports to accommodate visual observations and Laser-Doppler Anemometry measurements of fluid velocities. A set of experiments were conducted using liquid Nitrogen to determine the temperature stratification in the liquid and vapor, and pressure histories of the vapor during sudden and continuous depressurization for various different boundary and initial conditions. The study also includes the development and calibration of a computer model to simulate the experiments. This model is a one-dimensional, multi-node type which assumes the liquid and the vapor to be under non-equilibrium conditions during the depressurization. It has been tested for a limited number of cases. The preliminary results indicate that the accuracy of the simulations is determined by the accuracy of the heat transfer coefficients for the vapor and the liquid at the interface which are taken to be the calibration parameters in the present model. THE 3-D CFD MODELING OF GAS TURBINE COMBUSTOR-INTEGRAL BLEED FLOW INTERACTION **c07**
D. Y. Chen and R. S. Reynolds *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 359-380 Original contains color illustrations (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

An advanced 3-D Computational Fluid Dynamics (CFD) model was developed to analyze the flow interaction between a gas turbine combustor and an integral bleed plenum. In this model, the elliptic governing equations of continuity, momentum and the k-e turbulence model were solved on a boundary-fitted, curvilinear, orthogonal grid system. The model was first validated against test data from public literature and then applied to a gas turbine combustor with integral bleed. The model predictions agreed well with data from combustor rig testing. The model predictions also indicated strong flow interaction between the combustor and the integral bleed. Integral bleed flow distribution was found to have a great effect on the pressure distribution around the gas turbine combustor. Author

NUMERICAL ANALYSIS OF A VORTEX CONTROLLED DIFFUSER
Robert E. Spall *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 381-393 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

A numerical study of a prototypical vortex controlled diffuser is performed. The basic diffuser geometry consists of a step expansion in a pipe of area ratio 2.25:1. The incompressible Reynolds averaged Navier-Stokes equations, employing the K-epsilon turbulence model, are solved. Results are presented for bleed rates ranging from 1 to 7 percent. Diffuser efficiencies in excess of 80 percent are obtained. Reattachment lengths are reduced by a factor of up to 3. These results are in qualitative agreement with previous experimental work. However, differences in some basic details of experimentally observed and the present numerically generated flowfields exist. The effect of swirl is also investigated. Author

THE 3-D NUMERICAL STUDY OF AIRFLOW IN THE COMPRESSOR/COMBUSTOR PREDIFFUSER AND DUMP DIFFUSER OF AN INDUSTRIAL GAS TURBINE **c37**
Ajay K. Agrawal and Tah-Teh Yang *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 395-409 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

This paper describes the 3D computations of a flow field in the compressor/combustor diffusers of an industrial gas turbine. The geometry considered includes components such as the combustor support strut, the transition piece and the impingement sleeve with discrete cooling air holes on its surface. Because the geometry was complex and 3D, the airflow path was divided into two computational domains sharing an interface region. The body-fitted grid was generated independently in each of the two domains. The governing equations for incompressible Navier-Stokes equations were solved using the finite volume approach. The results show that the flow in the prediffuser is strongly coupled with the flow in the dump diffuser and vice versa. The computations also revealed that the flow in the dump diffuser is highly nonuniform. Author

TRANSIENT STUDIES OF CAPILLARY-INDUCED FLOW

M. K. Reagan and W. J. Bowman *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 429-438 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

This paper presents the numerical and experimental results of a study performed on the transient rise of fluid in a capillary tube. The capillary tube problem provides an excellent mechanism from which to launch an investigation into the transient flow of a fluid in a porous wick structure where capillary forces must balance both adverse gravitational effects and frictional losses. For the study, a capillary tube, initially charged with a small volume of water, was lowered into a pool of water. The behavior of the column of fluid during the transient that followed as more water entered the tube from the pool was both numerically and experimentally studied. Author

THREE-DIMENSIONAL SOLIDIFICATION AND MELTING USING MAGNETIC FIELD CONTROL c76

George S. Dulikravich and Vineet Ahuja *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 449-464 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

A new two-fluid mathematical model for fully three dimensional steady solidification under the influence of an arbitrary acceleration vector and with or without an arbitrary externally applied steady magnetic field have been formulated and integrated numerically. The model includes Joule heating and allows for separate temperature dependent physical properties within the melt and the solid. Latent heat of phase change during melting/solidification was incorporated using an enthalpy method. Mushy region was automatically captured by varying viscosity orders of magnitude between liquidus and solidus temperature. Computational results were obtained for silicon melt solidification in a parallelepiped container cooled from above and from a side. The results confirm that the magnetic field has a profound influence on the solidifying melt flow field thus changing convective heat transfer through the boundaries and the amount and shape of the solid accrued. This suggests that development of a quick-response algorithm for active control of three dimensional solidification is feasible since it would require low strength magnetic fields. Author (revised)

UNSTEADY THREE-DIMENSIONAL THERMAL FIELD PREDICTION IN TURBINE BLADES USING NONLINEAR BEM

Thomas J. Martin and George S. Dulikravich *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 467-476 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

A time-and-space accurate and computationally efficient fully three dimensional unsteady temperature field analysis computer code has been developed for truly arbitrary configurations. It uses boundary element method (BEM) formulation based on an unsteady Green's function approach, multi-point Gaussian quadrature spatial integration on each panel, and a highly clustered time-step integration. The code accepts either temperatures or heat fluxes as boundary conditions that can vary in time on a point-by-point basis. Comparisons of the BEM numerical results and known analytical unsteady results for simple shapes demonstrate very high accuracy and reliability of the algorithm. An example of computed three dimensional temperature and heat flux fields in a realistically shaped internally cooled turbine blade is also discussed. Author (revised)

A DUAL RECIPROCAL BOUNDARY ELEMENT FORMULATION FOR VISCOUS FLOWS

Olu Lafe *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 477-487 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The advantages inherent in the boundary element method (BEM) for potential flows are exploited to solve viscous flow problems. The trick is the introduction of a so-called dual reciprocal technique in which the convective terms are represented by a global function whose unknown coefficients are determined by collocation. The approach, which is necessarily iterative, converts the governing partial differential equations into integral equations via the distribution of fictitious sources or dipoles of unknown strength on the boundary. These integral equations consist of two parts. The first is a boundary integral term, whose kernel is the unknown strength of the fictitious sources and the fundamental solution of a convection-free flow problem. The second part is a domain integral term whose kernel is the convective portion of the governing PDEs. The domain integration can be transformed to the boundary by using the dual reciprocal (DR) concept. The resulting formulation is a pure boundary integral computational process. Author (revised)

A THEOREM REGARDING ROOTS OF THE ZERO-ORDER BESSEL FUNCTION OF THE FIRST KIND

X.-A. Lin and O. P. Agrawal *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 489-498 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

This paper investigates a problem on the steady-state, conduction-convection heat transfer process in cylindrical porous heat exchangers. The governing partial differential equations for the system are obtained using the energy conservation law. Solution of these equations and the concept of enthalpy lead to a new approach to prove a theorem that the sum of inverse squares of all the positive roots of the zero order Bessel function of the first kind equals to one-forth. As a corollary, it is shown that the sum of one over pth power (p greater than or equal to 2) of the roots converges to some constant. Author (revised)

AN APPLICATION OF SMALL-GAP EQUATIONS IN SEALING DEVICES

Carlos A. Vionnet and Juan C. Heinrich *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 499-512 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

The study of a thin, incompressible Newtonian fluid layer trapped between two almost parallel, sliding surfaces has been actively pursued in the last decades. This subject includes lubrication applications such as slider bearings or the sealing of non-pressurized fluids with rubber rotary shaft seals. In the present work we analyze numerically the flow of lubricant fluid through a micro-gap of sealing devices. The first stage of this study is carried out assuming that a 'small-gap' parameter delta attains an extreme value in the Navier-Stokes equations. The precise meaning of small-gap is achieved by the particular limit delta = 0 which, within the bounds of the hypotheses, predicts transport of lubricant through the sealed area by centrifugal instabilities. Numerical results obtained with the penalty function approximation in the finite element method are presented. In particular, the influence of inflow and outflow boundary conditions, and their impact in the simulated flow, are discussed. Author (revised)

COMPARISON OF NUMERICAL SIMULATION AND EXPERIMENTAL DATA FOR STEAM-IN-PLACE STERILIZATION

Jack H. Young and William C. Lasher *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 513-522 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

A complex problem involving convective flow of a binary mixture containing a condensable vapor and noncondensable gas in a partially enclosed chamber was modelled and results compared to transient experimental values. The finite element model successfully predicted transport processes in dead-ended tubes with inside diameters of 0.4 to 1.0 cm. When buoyancy driven convective flow was dominant, temperature and mixture compositions agreed with experimental data. Data from 0.4 cm tubes indicate diffusion to be the primary air removal method in small diameter tubes and the diffusivity value in the model to be too large. Author

A COMPARATIVE STUDY OF COMPUTATIONAL SOLUTIONS TO FLOW OVER A BACKWARD-FACING STEP

M. Mizukami, N. J. Georgiadis, and M. R. Cannon *In its* The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 523-530 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

A comparative study was conducted for computational fluid dynamic solutions to flow over a backward-facing step. This flow is a benchmark problem, with a simple geometry, but involves complicated flow physics such as free shear layers, reattaching flow, recirculation, and high turbulence intensities. Three Reynolds-averaged Navier-Stokes flow solvers with k-epsilon turbulence models were used, each using a different solution algorithm: finite difference, finite element, and hybrid finite element - finite difference. Comparisons were made with existing experimental data. Results showed that velocity profiles and reattachment lengths were predicted reasonably well by all three methods, while the skin friction coefficients were more difficult to predict accurately. It was noted that, in general, selecting an appropriate solver for each problem to be considered is important. Author

RESPONSE-COEFFICIENT METHOD FOR HEAT-CONDUCTION TRANSIENTS WITH TIME-DEPENDENT INPUTS

Tamer Ceylan *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 531-537 (For primary document see N94-23634 06-34)
Avail: CASI HC A02/MF A04; 5 functional color pages

A theoretical overview of the response coefficient method for heat conduction transients with time-dependent input forcing functions is presented with a number of illustrative applications. The method may be the most convenient and economical if the same problem is to be solved many times with different input-time histories or if the solution time is relatively long. The method is applicable to a wide variety of problems, including irregular geometries, position-dependent boundary conditions, position-dependent physical properties, and nonperiodic irregular input histories. Nonuniform internal energy generation rates within the structure can also be handled by the method. The area of interest is long-time solutions, in which initial condition is unimportant, and not the early transient period. The method can be applied to one dimensional problems in cartesian, cylindrical, and spherical coordinates as well as to two dimensional problems in cartesian and cylindrical coordinates. UPWIND MACCORMACK EULER SOLVER WITH NON-EQUILIBRIUM CHEMISTRY c61

Scott E. Sherer and James N. Scott *In* NASA. Lewis Research Center, The Fifth Annual Thermal and Fluids Analysis Workshop Nov. 1993 p 539-552 (For primary document see N94-23634 06-34)
Avail: CASI HC A03/MF A04; 5 functional color pages

A computer code, designated UMPIRE, is currently under development to solve the Euler equations in two dimensions with non-equilibrium chemistry. UMPIRE employs an explicit MacCormack algorithm with dissipation introduced via Roe's flux-difference split upwind method. The code also has the capability to employ a point-implicit methodology for flows where stiffness is introduced through the chemical source term. A technique consisting of diagonal sweeps across the computational domain from each corner is presented, which is used to reduce storage and execution requirements. Results depicting one dimensional shock tube flow for both calorically perfect gas and thermally perfect, dissociating nitrogen are presented to verify current capabilities of the program. Also, computational results from a chemical reactor vessel with no fluid dynamic effects are presented to check the chemistry capability and to verify the point implicit strategy. Author

INVESTIGATIONS ON DETONATION SHOCK DYNAMICS AND RELATED TOPICS

D. S. Stewart 1993 308 p Prepared in cooperation with Illinois Univ., Urbana
(Contract W-7405-eng-36)
(DE94-002570; LA-SUB-93-299) Avail: CASI HC A14/MF A03

A final report that summarizes the research findings and research activities between the University of Illinois and the University of California is presented. The main focus of the work was on investigations of Detonation Shock Dynamics. A second emphasis was on modeling compaction of energetic materials and deflagration to detonation in those materials. The work has led to a number of extensions of the theory of Detonation Shock Dynamics (DSD) and its application as an engineering design method for high explosive systems. The work also enhanced the hydrocode capabilities of researchers in M-Division by modifications to CAVEAT, an existing Los Alamos hydrocode. Linear stability studies of detonation flows were carried out for the purpose of code verification. This work also broadened the existing theory for detonation. The work in this contract led to the development of one-phase models for dynamic compaction of porous energetic materials and laid the groundwork for subsequent studies. Some work that modeled the discrete heterogeneous behavior of propellant beds was also performed. DOE

RELIABILITY IN SECOND MOMENT TURBULENCE CLOSURES REVISITED

Tsan-Hsing Shih, Aamir Shabbir, and John L. Lumley (Cornell Univ., Ithaca, NY.) Jan. 1994 68 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106469; E-8336; NAS 1.15:106469; ICOMP-93-51; CMOTT-93-18) Avail: CASI HC A04/MF A01

Realizability in turbulence modeling, i.e., the non-negativity of the normal Reynolds stresses and scalar variances and the Schwarz' inequality between any two fluctuating quantities, has been accepted as an important concept in the study of turbulence closures. Properly developed model equations based on realizability can prevent non-physical results and also reduce numerical stiffness. However, much confusion about the realizability concept has been created recently by Speziale et al. In order to provide a better understanding of realizability and its application in turbulence modeling, the following important subjects are discussed: the properties of general turbulent correlation matrices and the related realizability concept, the general realizability conditions and the method of their implementation. The detailed realizability constraints for various model terms in the second moment equations (including Reynolds stresses and scalar fluxes) that, we believe, are useful for developing more general turbulence models are presented. As an example, the realizable behavior of such realizably constrained second moment closures based on the work of Shih and Lumley for turbulent flows under various critical situations is demonstrated. For the purpose of comparisons, a recently proposed model by Speziale et al. that makes no attempt to satisfy realizability and the IP model of Launder, Reece and Rodi are also included. Comparisons clearly show the superior realizable behavior of the models based on realizability over that of the models not considering realizability. Author (revised)

HEAT PIPE VAPOR DYNAMICS Ph.D. Thesis
Farrokh Issacci 1990 172 p
(Grant NAG3-899)
(NASA-CR-194217; NAS 1.26:194217) Avail: CASI HC A08/MF A02

The dynamic behavior of the vapor flow in heat pipes is investigated at startup and during operational transients. The vapor is modeled as two-dimensional, compressible viscous flow in an enclosure with inflow and outflow boundary conditions. For steady-state and operating transients, the SIMPLER method is used. In this method a control volume approach is employed on a staggered grid which makes the scheme very stable. It is shown that for relatively low input heat fluxes the compressibility of the vapor flow is low and the SIMPLER scheme is suitable for the study of transient vapor dynamics. When the input heat flux is high or the process under a startup operation starts at very low pressures and temperatures, the vapor is highly compressible and a shock wave is created in the evaporator. It is shown that for a wide range of input heat fluxes, the standard methods, including the SIMPLER scheme, are not suitable. A nonlinear filtering technique, along with the centered difference scheme, are then used for shock capturing as well as for the solution of the cell Reynolds-number problem. For high heat flux, the startup transient phase involves multiple shock reflections in the evaporator region. Each shock reflection causes a significant increase in the local pressure and a large pressure drop along the heat pipe. Furthermore, shock reflections cause flow reversal in the evaporation region and flow circulations in the adiabatic region. The maximum and maximum-averaged pressure drops in different sections of the heat pipe oscillate periodically with time because of multiple shock reflections. The pressure drop converges to a constant value at steady state. However, it is significantly higher than its steady-state value at the initiation of the startup transient. The time for the vapor core to reach steady-state condition depends on the input heat flux, the heat pipe geometry, the working fluid, and the condenser conditions. However, the vapor transient time, for an Na-filled heat pipe is on the order of seconds. Depending on the time constant for the overall system, the vapor transient time may be very short. Therefore, the vapor core may be assumed to be quasi-steady in the transient analysis of a heat pipe operation. Author

SKIN FRICTION MEASUREMENT IN COMPLEX FLOWS USING THIN OIL FILM TECHNIQUES Final Report, 1 Oct. 1989 - 31 Oct. 1993
31 Jan. 1994 7 p
(Grant NAG2-261)
(NASA-CR-194872; NAS 1.26:194872) Avail: CASI HC A02/MF A01

The NASA Grant NAG2-261 was initiated to support a program of research to study complex flows that occur in flight and laboratory experiments by building, testing and optimizing an on-board technique for direct measurement of surface shear stress using thin oil film techniques. The program of research has proceeded under the supervision of the NASA Ames Research Center and with further cooperation from the NASA Ames-Dryden and NASA Langley Research Centers. In accordance with the original statement of work, the following research milestones were accomplished: (1) design and testing of an internally mounted one-directional skin friction meter to demonstrate the feasibility of the concept; (2) design and construction of a compact instrument capable of measuring skin friction in two directions; (3) study of transitional and fully turbulent boundary layers over a flat plate with and without longitudinal pressure gradients utilizing the compact two-directional skin friction meter; (4) study of the interaction between a turbulent boundary layer and a shock wave generated by a compression corner using the two-directional meter; and (5) flight qualification of the compact meter and accompanying electronic and pneumatic systems, preliminary installation into flight test fixture.

The 1993 annual progress reports of the Research Fellow and students of the Center for Turbulence Research are included. The first group of reports are directed towards the theory and application of active control in turbulent flows including the development of a systematic mathematical procedure based on the Navier Stokes equations for flow control. The second group of reports are concerned with the prediction of turbulent flows. The remaining articles are devoted to turbulent reacting flows, turbulence physics, experiments, and simulations. For individual titles, see N94-24139 through N94-24169.

Feedback control equations were developed and tested for computing wall normal control velocities to control turbulent flow in a channel with the objective of reducing drag. The technique used is the minimization of a 'cost functional' which is constructed to represent some balance of the drag integrated over the wall and the net control effort. A distribution of wall velocities is found which minimizes this cost functional some time shortly in the future based on current observations of the flow near the wall. Preliminary direct numerical simulations of the scheme applied to turbulent channel flow indicates it provides approximately 17 percent drag reduction. The mechanism apparent when the scheme is applied to a simplified flow situation is also discussed. Author (revised)

DRAG REDUCTION AT A PLANE WALL
D. C. Hill *In its* Annual Research Briefs, 1993 Dec. 1993 p 15-19
(For primary document see N94-24138 06-34)
Avail: CASI HC A01/MF A04

The objective is to determine by analytical means how drag on a plane wall may be modified favorably using a minimal amount of flow information - preferably only information at the wall. What quantities should be measured? How should that information be assimilated in order to arrive at effective control? As a prototypical problem, incompressible, viscous flow, governed by the Navier-Stokes equations, past a plane wall at which the no-slip condition was modified was considered. The streamwise and spanwise velocity components are required to be zero, but the normal component is to be specified according to some control law. The challenge is to choose the wall-normal velocity component based on flow conditions at the wall so that the mean drag is as small as possible. There can be no net mass flux through the wall, and the total available control energy is constrained. A turbulent flow is highly unsteady and has detailed spatial structure. The mean drag on the wall is the integral over the wall of the local shear forces exerted by the fluid, which is then averaged in time; it is a 'macroscopic' property of the flow. It is not obvious how unsteady boundary control is to be applied in order to modify the mean flow most effectively, especially in view of the non- self-adjoint nature of the governing equations. An approximate analytical solution to the suboptimal scheme is pursued. Author (revised)

BOUNDARY LAYER RECEPTIVITY AND CONTROL
D. C. Hill *In its* Annual Research Briefs, 1993 Dec. 1993 p 21-29
(For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

Receptivity processes initiate natural instabilities in a boundary layer. The instabilities grow and eventually break down to turbulence. Consequently, receptivity questions are a critical element of the analysis of the transition process. Success in modeling the physics of receptivity processes thus has a direct bearing on technological issues of drag reduction. The means by which transitional flows can be controlled is also a major concern: questions of control are tied inevitably to those of receptivity. Adjoint systems provide a highly effective mathematical method for approaching many of the questions associated with both receptivity and control. The long term objective is to develop adjoint methods to handle increasingly complex receptivity questions, and to find systematic procedures for deducing effective control strategies. The most elementary receptivity problem is that in which a parallel boundary layer is forced by time-harmonic sources of various types. The characteristics of the response to such forcing form the building blocks for more complex receptivity mechanisms. The first objective of this year's research effort was to investigate how a parallel Blasius boundary layer responds to general direct forcing. Acoustic disturbances in the freestream can be scattered by flow non-uniformities to produce Tollmien-Schlichting waves. For example, scattering by surface roughness is known to provide an efficient receptivity path. The present effort is directed towards finding a solution by a simple adjoint analysis, because adjoint methods can be extended to more complex problems. In practice, flows are non-parallel and often three-dimensional. Compressibility may also be significant in some cases. Recent developments in the use of Parabolized Stability Equations (PSE) offer a promising possibility. By formulating and solving a set of adjoint parabolized equations, a method for mapping the efficiency with which external forcing excites the three-dimensional motions of a non-parallel boundary layer was developed. The method makes use of the same computationally efficient formulation that makes the PSE currently so appealing. In the area of flow control, adjoint systems offer a powerful insight into the effect of control forces. One of the simplest control strategies for boundary layers involves the application of localized mean wall suction. Author (revised)

TOWARD MODELING WINGTIP VORTICES c02
O. Zeman *In its* Annual Research Briefs, 1993 Dec. 1993 p 31-40 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

Wingtip vortices are generated by lifting airfoils; their salient features are compactness and relatively slow rate of decay. The principal motivation for studying the far field evolution of wingtip vortices is the need to understand and predict the extent of the vortex influence during aircraft take-off or landing. On submarines a wingtip vortex ingested into a propeller can be a source of undesirable noise. The main objectives of this research are (1) to establish theoretical understanding of the principal mechanisms that govern the later (diffusive) stages of a turbulent vortex, (2) to develop a turbulence closure model representing the basic physical mechanisms that control the vortex diffusive stage, and further (3) to investigate coupling between the near and far field evolutions; in other words, to study the effect of initial conditions on the vortex lifetime and the ultimate state. NEW CONCEPTS FOR REYNOLDS STRESS TRANSPORT EQUATION MODELING OF INHOMOGENEOUS FLOWS c02
J. Blair Perot and Parviz Moin *In its* Annual Research Briefs, 1993 Dec. 1993 p 41-65 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

The ability to model turbulence near solid walls and other types of boundaries is important in predicting complex engineering flows. Most turbulence modeling has concentrated either on flows which are nearly homogeneous or isotropic, or on turbulent boundary layers. Boundary layer models usually rely very heavily on the presence of mean shear and the production of turbulence due to that mean shear. Most other turbulence models are based on the assumption of quasi-homogeneity. However, there are many situations of engineering interest which do not involve large shear rates and which are not quasi-homogeneous or isotropic. Shear-free turbulent boundary layers are the prototypical example of such flows, with practical situations being separation and reattachment, bluff body flow, high free-stream turbulence, and free surface flows. Although these situations are not as common as the variants of the flat plate turbulent boundary layer, they tend to be critical factors in complex engineering situations. The models developed are intended to extend classical quasi-homogeneous models into regions of large inhomogeneity. These models do not rely on the presence of mean shear or production, but are still applicable when those additional effects are included. Although the focus is on shear-free boundary layers as tests for these models, results for standard shearing boundary layers are also shown. Author (revised)

COMPUTATION OF TURBULENT FLOWS OVER BACKWARD AND FORWARD-FACING STEPS USING A NEAR-WALL REYNOLDS STRESS MODEL c02
Sung Ho Ko *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 75-90 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

Separation and reattachment of turbulent shear layers is observed in many important engineering applications, yet it is poorly understood. This has motivated many studies on understanding and predicting the processes of separation and reattachment of turbulent shear layers. Both of the situations in which separation is induced by adverse pressure gradient, or by discontinuities of geometry, have attracted attention of turbulence model developers. Formulation of turbulence closure models to describe the essential features of separated turbulent flows accurately is still a formidable task. Computations of separated flows associated with sharp-edged bluff bodies are described. For the past two decades, the backward-facing step flow, the simplest separated flow, has been a popular test case for turbulence models. Detailed studies on the performance of many turbulence models, including two equation turbulence models and Reynolds stress models, for flows over steps can be found in the papers by Thangam & Speziale and Lasher & Taulbee). These studies indicate that almost all the existing turbulence models fail to accurately predict many important features of back step flow such as reattachment length, recovery rate of the redeveloping boundary layers downstream of the reattachment point, streamlines near the reattachment point, and the skin friction coefficient. The main objectives are to calculate flows over backward and forward-facing steps using the NRSM and to make use of the newest DNS data for detailed comparison. This will give insights for possible improvements of the turbulence model. Author (revised)

LARGE EDDY SIMULATION OF A BOUNDARY LAYER WITH CONCAVE STREAMWISE CURVATURE
Thomas S. Lund *In its* Annual Research Briefs, 1993 Dec. 1993 p 91-99 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

One of the most exciting recent developments in the field of large eddy simulation (LES) is the dynamic subgrid-scale model. The dynamic model concept is a general procedure for evaluating model constants by sampling a band of the smallest scales actually resolved in the simulation. To date, the procedure has been used primarily in conjunction with the Smagorinsky model. The dynamic procedure has the advantage that the value of the model constant need not be specified a priori, but rather is calculated as a function of space and time as the simulation progresses. This feature makes the dynamic model especially attractive for flows in complex geometries where it is difficult or impossible to calibrate model constants. The dynamic model was highly successful in benchmark tests involving homogeneous and channel flows. Having demonstrated the potential of the dynamic model in these simple flows, the overall direction of the LES effort at CTR shifted toward an evaluation of the model in more complex situations. The current test cases are basic engineering-type flows for which Reynolds averaged approaches were unable to model the turbulence to within engineering accuracy. Flows currently under investigation include a backward-facing step, wake behind a circular cylinder, airfoil at high angles of attack, separated flow in a diffuser, and boundary layer over a concave surface. Preliminary results from the backward-facing step and cylinder wake simulations are encouraging. Progress on the LES of a boundary layer on a concave surface is discussed. Although the geometry of a concave wall is not very complex, the boundary layer that develops on its surface is difficult to model due to the presence of streamwise Taylor-Gortler vortices. These vortices arise as a result of a centrifugal instability associated with the convex curvature. Author (revised)

LARGE-EDDY SIMULATION OF FLOW IN A PLANE, ASYMMETRIC DIFFUSER

Hans-Jakob Kaltenbach *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 101-109 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

Recent improvements in subgrid-scale modeling as well as increases in computer power make it feasible to investigate flows using large-eddy simulation (LES) which have been traditionally studied with techniques based on Reynolds averaging. However, LES has not yet been applied to many flows of immediate technical interest. Preliminary results from LES of a plane diffuser flow are described. The long term goal of this work is to investigate flow separation as well as separation control in ducts and ramp-like geometries. Author (revised)

ON THE LARGE EDDY SIMULATION OF TURBULENT FLOWS IN COMPLEX GEOMETRY
Sandip Ghosal *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 111-128 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

Application of the method of Large Eddy Simulation (LES) to a turbulent flow consists of three separate steps. First, a filtering operation is performed on the Navier-Stokes equations to remove the small spatial scales. The resulting equations that describe the space time evolution of the 'large eddies' contain the subgrid-scale (sgs) stress tensor that describes the effect of the unresolved small scales on the resolved scales. The second step is the replacement of the sgs stress tensor by some expression involving the large scales - this is the problem of 'subgrid-scale modeling'. The final step is the numerical simulation of the resulting 'closed' equations for the large scale fields on a grid small enough to resolve the smallest of the large eddies, but still much larger than the fine scale structures at the Kolmogorov length. In dividing a turbulent flow field into 'large' and 'small' eddies, one presumes that a cut-off length delta can be sensibly chosen such that all fluctuations on a scale larger than delta are 'large eddies' and the remainder constitute the 'small scale' fluctuations. Typically, delta would be a length scale characterizing the smallest structures of interest in the flow. In an inhomogeneous flow, the 'sensible choice' for delta may vary significantly over the flow domain. For example, in a wall bounded turbulent flow, most statistical averages of interest vary much more rapidly with position near the wall than far away from it. Further, there are dynamically important organized structures near the wall on a scale much smaller than the boundary layer thickness. Therefore, the minimum size of eddies that need to be resolved is smaller near the wall. In general, for the LES of inhomogeneous flows, the width of the filtering kernel delta must be considered to be a function of position. If a filtering operation with a nonuniform filter width is performed on the Navier-Stokes equations, one does not in general get the standard large eddy equations. The complication is caused by the fact that a filtering operation with a nonuniform filter width in general does not commute with the operation of differentiation. This is one of the issues that we have looked at in detail as it is basic to any attempt at applying LES to complex geometry flows. Our principal findings are summarized. Author (revised)

DYNAMIC LOCALIZATION AND SECOND-ORDER SUBGRID-SCALE MODELS IN LARGE EDDY SIMULATIONS OF CHANNEL FLOW
William H. Cabot *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 129-144 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

The objective here is to test the Dynamic Localization (DL) model in a wall-bounded channel flow for numerical stability and accuracy of results. Algebraic stress models suggest that the model for the residual subgrid-scale (SGS) Reynolds stress and scalar flux should generally have terms comprising most of the unique products of the resolved strain (S) and rotation (R) tensors with S and the resolved scalar gradient. The standard dynamic SGS model uses a simple (Smagorinsky) base model for the residual Reynolds stress, which is made proportional to S, and down-gradient base models for residual scalar fluxes; these correspond to the lowest, 'first-order' terms in algebraic stress models. Temporal scaling terms in these base models are formed from the magnitude of the resolved strain rate. While this is appropriate for simple shear flows, it may not be appropriate for more complicated flows (relevant to geophysical and astrophysical problems) that include any combination of shear, rotation, buoyancy, etc. On the other hand, the coefficient in the dynamic SGS model readily adjusts itself to different flow conditions and may adequately take account of these effects without the need for more complicated base models. Cabot (1993) has begun to test the dynamic SGS model in buoyant flows (Rayleigh-Benard and internally heated convection) with and without buoyancy terms explicitly included in the scaling terms of the base model; no great differences were found in large eddy simulation (LES) results for the different base model scalings. The second objective in this work is to test base models with additional, 'second-order' terms (e.g., S(sup 2) and RS for the residual Reynolds stress). These terms have been found to improve large-scale flow predictions by kappa-epsilon models in the presence of rotation and shear. Second-order base models will be tested here in the LES of channel flow with and without solid-body rotation and compared with results from the standard first-order base models to determine if there are significant differences or improvements in results that would warrant the added complexity of the second-order base models. TOWARD LARGE EDDY SIMULATION OF TURBULENT FLOW OVER AN AIRFOIL c02
Haecheon Choi *In its* Annual Research Briefs, 1993 Dec. 1993 p 145-149 (For primary document see N94-24138 06-34)
Avail: CASI HC A01/MF A04

The flow field over an airfoil contains several distinct flow characteristics, e.g. laminar, transitional, turbulent boundary layer flow, flow separation, unstable free shear layers, and a wake. This diversity of flow regimes taxes the presently available Reynolds averaged turbulence models. Such models are generally tuned to predict a particular flow regime, and adjustments are necessary for the prediction of a different flow regime. Similar difficulties are likely to emerge when the large eddy simulation technique is applied with the widely used Smagorinsky model. This model has not been successful in correctly representing different turbulent flow fields with a single universal constant and has an incorrect near-wall behavior. Germano et al. (1991) and Ghosal, Lund & Moin have developed a new subgrid-scale model, the dynamic model, which is very promising in alleviating many of the persistent inadequacies of the Smagorinsky model: the model coefficient is computed dynamically as the calculation progresses rather than input a priori. The model has been remarkably successful in prediction of several turbulent and transitional flows. We plan to simulate turbulent flow over a '2D' airfoil using the large eddy simulation technique. Our primary objective is to assess the performance of the newly developed dynamic subgrid-scale model for computation of complex flows about aircraft components and to compare the results with those obtained using the Reynolds average approach and experiments. The present computation represents the first application of large eddy simulation to a flow of aeronautical interest and a key demonstration of the capabilities of the large eddy simulation technique. UNSTRUCTURED GRID LARGE EDDY SIMULATION OF WALL BOUNDED TURBULENT FLOWS
Kenneth Jansen *In its* Annual Research Briefs, 1993 Dec. 1993 p 151-156 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

Historically, large eddy simulations (LES) have been restricted to simple geometries where spectral or finite difference methods have dominated due to their efficient use of structured grids. Structured grids, however, not only have difficulty representing complex domains and adapting to complicated flow features, but also are rather inefficient for simulating flows at high Reynolds numbers. The lack of efficiency stems from the need to resolve the viscous sub layer which requires very fine resolution in all three directions near the wall. Structured grids make use of a stretching to reduce the normal grid spacing but must carry the fine resolution in the streamwise and spanwise directions throughout the domain. The unnecessarily fine grid for much of the domain leads to disturbingly high grid estimates. Chapman (1979), and later Moin & Jimenez (1993), pointed out that, in order to advance the technology to airfoils at flight Reynolds numbers, structured grids must be abandoned in lieu of what are known as nested or unstructured grids. We illustrate the ability of an unstructured mesh to refine only the near wall region. Note the large number of points near the wall (where the fine vortical features need better resolution) and the coarseness in all directions away from the wall (where the scales are much larger). The important difference between this approach and the usual structured grid stretching is that the number of elements used to discretize the spanwise and streamwise features of the flow is reduced in each successive layer coming off the wall. This is due to the fact that the elements not only grow in the normal direction, but in the other directions as well. This greatly reduces the total number of points or elements required for a given Reynolds number flow. Derived from text

Study of turbulent flows in rotating reference frames has long been an area of considerable scientific and engineering interest. Because of its importance, the subject of turbulence in rotating reference frames has motivated over the years a large number of theoretical, experimental, and computational studies. The bulk of these previous works has served to demonstrate that the effect of system rotation on turbulence is subtle and remains exceedingly difficult to predict. A rotating flow of particular interest in many studies, including the present work, is examination of the effect of solid-body rotation on an initially isotropic turbulent flow. One of the principal reasons for the interest in this flow is that it represents the most basic turbulent flow whose structure is altered by system rotation but without the complicating effects introduced by mean strains or flow inhomogeneities. The assumption of statistical homogeneity considerably simplifies analysis and computation. The principal objective of the present study has been to examine the asymptotic state of solid-body rotation applied to an initially isotropic, high Reynolds number turbulent flow. Of particular interest has been to determine the degree of two-dimensionalization and the existence of asymptotic self-similar states in homogeneous rotating turbulence. Derived from text

ENERGY TRANSFER AND CONSTRAINED SIMULATIONS IN ISOTROPIC TURBULENCE

Javier Jimenez *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 171-186 (For primary document see N94-24138 06-34)

Avail: CASI HC A03/MF A04

The defining characteristic of turbulent flows is their ability to dissipate energy, even in the limit of zero viscosity. The Euler equations, if constrained in such a way that the velocity derivatives remain bounded, conserve energy. But when they arise as the limit of the Navier-Stokes (NS) equations, when the Reynolds number goes to infinity, there is persuasive empirical evidence that the gradients become singular as just the right function of Re for the dissipation to remain non-zero and to approach a well defined limit. It is generally believed that this limiting value of the dissipation is a property of the Euler equations themselves, independent of the particular dissipative mechanism involved, and that it can be normalized with the large scale properties of the turbulent flow (e.g. the kinetic energy per unit volume u'(exp 2)/2, and the integral scale L) without reference to the Reynolds number or to other dissipative quantities. This is usually taken to imply that the low wave number end of the energy spectrum, far from the dissipative range, is also independent of the particular mechanism chosen to dispose of the energy transfer. In the following sections, we present some numerical experiments on the effect of substituting different dissipation models into the truncated Euler equations. We will see that the effect is mainly felt in the 'near dissipation' range of the energy spectrum, but that this range can be quite wide in some cases, contaminating a substantial range of wave numbers. In the process, we will develop a 'practical' approximation to the subgrid energy transfer in isotropic turbulence, and we will gain insight into the structure of the nonlinear interactions among turbulent scales of comparable size, and into the nature of energy backscatter. Some considerations on future research directions are offered at the end. Derived from text

A LARGE EDDY SIMULATION SCHEME FOR TURBULENT REACTING FLOWS

Feng Gao *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 187-194 (For primary document see N94-24138 06-34)

Avail: CASI HC A02/MF A04

The recent development of the dynamic subgrid-scale (SGS) model has provided a consistent method for generating localized turbulent mixing models and has opened up great possibilities for applying the large eddy simulation (LES) technique to real world problems. Given the fact that the direct numerical simulation (DNS) can not solve for engineering flow problems in the foreseeable future (Reynolds 1989), the LES is certainly an attractive alternative. It seems only natural to bring this new development in SGS modeling to bear on the reacting flows. The major stumbling block for introducing LES to reacting flow problems has been the proper modeling of the reaction source terms. Various models have been proposed, but none of them has a wide range of applicability. For example, some of the models in combustion have been based on the flamelet assumption which is only valid for relatively fast reactions. Some other models have neglected the effects of chemical reactions on the turbulent mixing time scale, which is certainly not valid for fast and non-isothermal reactions. The probability density function (PDF) method can be usefully employed to deal with the modeling of the reaction source terms. In order to fit into the framework of LES, a new PDF, the large eddy PDF (LEPDF), is introduced. This PDF provides an accurate representation for the filtered chemical source terms and can be readily calculated in the simulations. The details of this scheme are described. Derived from text

THE COMBUSTION PROGRAM AT CTR c25

Thierry J. Poinsot *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 195-203 (For primary document see N94-24138 06-34)

Avail: CASI HC A02/MF A04

Understanding and modeling of turbulent combustion are key problems in the computation of numerous practical systems. Because of the lack of analytical theories in this field and of the difficulty of performing precise experiments, direct numerical simulation (DNS) appears to be one of the most attractive tools to use in addressing this problem. The general objective of DNS of reacting flows is to improve our knowledge of turbulent combustion but also to use this information for turbulent combustion models. For the foreseeable future, numerical simulation of the full three-dimensional governing partial differential equations with variable density and transport properties as well as complex chemistry will remain intractable; thus, various levels of simplification will remain necessary. On one hand, the requirement to simplify is not necessarily a handicap: numerical simulations allow the researcher a degree of control in isolating specific physical phenomena that is inaccessible in experiments. CTR has pursued an intensive research program in the field of DNS for turbulent reacting flows since 1987. DNS of reacting flows is quite different from DNS of non-reacting flows: without reaction, the equations to solve are clearly the five conservation equations of the Navier Stokes system for compressible situations (four for incompressible cases), and the limitation of the approach is the Reynolds number (or in other words the number of points in the computation). For reacting flows, the choice of the equations, the species (each species will require one additional conservation equation), the chemical scheme, and the configuration itself is more complex. STRETCH-INDUCED QUENCHING IN FLAME-VORTEX INTERACTIONS c25

J.-M. Samaniego *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 205-218 (For primary document see N94-24138 06-34)

Avail: CASI HC A03/MF A04

The flame-vortex interaction problem is a natural configuration in which several issues relevant to turbulent combustion can be addressed: effect of strain-rate and curvature, effect of the Lewis number, effect of heat losses, effect of complex chemistry, and flame-generated turbulence. In such an approach, the interaction of an isolated vortex with a laminar premixed flame is viewed as a unit process of a turbulent premixed flame in which the reaction zone keeps a laminar like structure locally; this is precisely the case of the wrinkled flame or flamelet regime in turbulent combustion. The present work complements previous studies and involves the study of the interaction of a vortex pair and a laminar premixed flame in a planar two-dimensional geometry, together with numerical simulations. This geometry is quite unique since most studies have considered axisymmetric vortex rings. Such a geometry offers several advantages over previous studies. Derived from text

A TRANSPORT EQUATION FOR THE SCALAR DISSIPATION IN REACTING FLOWS WITH VARIABLE DENSITY: FIRST RESULTS

T. Mantel *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 219-228 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

Although the different regimes of premixed combustion are not well defined, most of the recent developments in turbulent combustion modeling are led in the so-called flamelet regime. The goal of these models is to give a realistic expression to the mean reaction rate (w). Several methods can be used to estimate (w). Bray and coworkers (Libby & Bray 1980, Bray 1985, Bray & Libby 1986) express the instantaneous reaction rate by means of a flamelet library and a frequency which describes the local interaction between the laminar flamelets and the turbulent flowfield. In another way, the mean reaction rate can be directly connected to the flame surface density (Sigma). This quantity can be given by the transport equation of the coherent flame model initially proposed by Marble & Broadwell 1977 and developed elsewhere. The mean reaction rate, (w), can also be estimated thanks to the evolution of an arbitrary scalar field G(x, t) = G(sub O) which represents the flame sheet. G(x, t) is obtained from the G-equation proposed by Williams 1985, Kerstein et al. 1988 and Peters 1993. Another possibility proposed in a recent study by Mantel & Borghi 1991, where a transport equation for the mean dissipation rate (epsilon(sub c)) of the progress variable c is used to determine (w). In their model, Mantel & Borghi 1991 considered a medium with constant density and constant diffusivity in the determination of the transport equation for (epsilon(sub c)). A comparison of different flamelet models made by Duclos et al. 1993 shows the realistic behavior of this model even in the case of constant density. Our objective in this present report is to present preliminary results on the study of this equation in the case of variable density and variable diffusivity. Assumptions of constant pressure and a Lewis number equal to unity allow us to significantly simplify the equation. A systematic order of magnitude analysis based on adequate scale relations is performed on each term of the equation. As in the case of constant density and constant diffusivity, the effects of stretching of the scalar field by the turbulent strain field, of local curvature, and of chemical reactions are predominant. In this preliminary work, we suggest closure models for certain terms, which will be validated after comparisons with DNS data. Derived from text

THE PRODUCTION OF PREMIXED FLAME SURFACE AREA IN TURBULENT SHEAR FLOW c25

A. Trouve *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 229-248 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A01

In the present work, we use three-dimensional Direct Numerical Simulation (DNS) of premixed flames in turbulent shear flow to characterize the effect of a mean shear motion on flame surface production. The shear is uniform in the unburnt gas, and simulations are performed for different values of the mean shear rate, S. The data base is then used to estimate and compare the different terms appearing in the Sigma-equation as a function of S. The analysis gives in particular the relative weights f the turbulent flow and mean flow components, a(sub T) and A(sub T), of the flame surface production term. This comparison indicates whether the dominant effects of a mean flow velocity gradient on flame surface area are implicit and scale with the modified turbulent flow parameters, kappa and epsilon, or explicit and scale directly with the rate of deformation. ON STREAK SPACING IN WALL-BOUNDED TURBULENT FLOWS

James M. Hamilton (Harvard Univ., Cambridge, MA.) and John J. Kim *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 249-257 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

The present study is a continuation of the examination by Hamilton et al. of the regeneration mechanisms of near-wall turbulence and an attempt to investigate the conjecture of Waleffe et al. The basis of this study is an extension of the 'minimal channel' approach of Jimenez and Moin that emphasizes the near-wall region and reduces the complexity of the turbulent flow by considering a plane Couette flow of near minimum Reynolds number and stream-wise and span-wise extent. Reduction of the flow Reynolds number to the minimum value which will allow turbulence to be sustained has the effect of reducing the ratio of the largest scales to the smallest scales or, equivalently, of causing the near-wall region to fill more of the area between the channel walls. A plane Couette flow was chosen for study since this type of flow has a mean shear of a single sign, and at low Reynolds numbers, the two wall regions are found to share a single set of structures. NUMERICAL SIMULATION OF NON-NEWTONIAN FREE SHEAR FLOWS

G. M. Homsy and J. Azaiez *In its* Annual Research Briefs, 1993 Dec. 1993 p 259-268 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

Free shear flows, like those of mixing layers, are encountered in aerodynamics, in the atmosphere, and in the ocean as well as in many industrial applications such as flow reactors or combustion chambers. It is, therefore, crucial to understand the mechanisms governing the process of transition to turbulence in order to predict and control the evolution of the flow. Delaying transition to turbulence as far downstream as possible allows a gain in energy expenditure while accelerating the transition can be of interest in processes where high mixing is desired. Various methods, including the use of polymer additives, can be effective in controlling fluid flows. The drag reduction obtained by the addition of small amounts of high polymers has been an active area of research for the last three decades. It is now widely believed that polymer additives can affect the stability of a large variety of flows and that dilute solutions of these polymers have been shown to produce drag reductions of over 80 percent in internal flows and over 60 percent in external flows under a wide range of conditions. The major thrust of this work is to study the effects of polymer additives on the stability of the incompressible mixing layer through large scale numerical simulations. In particular, we focus on the two dimensional flow and examine how the presence of viscoelasticity may affect the typical structures of the flow, namely roll-up and pairing of vortices. TRANSITION TO TURBULENCE IN AN ELLIPTIC VORTEX

Thomas S. Lundgren (Minnesota Univ., Minneapolis.) and N. N. Mansour *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 269-284 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

We study the three dimensional instability and nonlinear growth of the two dimensional flow described by the stream function Psi = (A sin b1 x sin b2 y)/(b1(exp 2) + b2(exp 2)) where b1 = pi/L1, b2 = pi/L2. This is a swirling flow in a box which is bounded by 0 less than x less than L1, 0 less than y less than L2 and is infinite in the z direction. This flow is a solution of the Navier-Stokes equation with A = exp(-v(b1(exp 2) + b2(exp 2))t) which slowly decays. We seek a viscous solution which starts near this one and slips along but does not penetrate the bounding walls. The vorticity of the basic flow is w(sub z) = A sin b1 x sin b2 y which has maximum value A at the center of the box and drops to zero at the boundaries. We can think of the resulting flow as that of a captive vortex. Derived from text

VORTICAL STRUCTURE IN A FORCED PLANE MIXING LAYER

Richard L. LeBoeuf *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 285-298 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

The objective of this phase of an ongoing study is to obtain detailed three dimensional phase-averaged measurements of forced mixing layer vorticity development and evolution. Acoustic forcing is being used to phase-lock the initial development and subsequent pairing of the span wise vortical structures. Phase averaged measurements of the three velocity components will permit the study of three dimensional vorticity distributions without invoking Taylor's hypothesis which is known to introduce uncertainty. Currently two sine waves, one at the fundamental roll-up frequency and the second, its subharmonic, are being used to force the initial roll-up and first pairing of the span wise rollers. The two dimensional measurements described in this report were obtained in order to determine the best operating conditions for the detailed three dimensional study of the mixing layer undergoing pairing via various pairing mechanisms. SOUND RADIATION DUE TO BOUNDARY LAYER TRANSITION c71
Meng Wang *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 299-312 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

This report describes progress made to date towards calculations of noise produced by the laminar-turbulence transition process in a low Mach number boundary layer formed on a rigid wall. The primary objectives of the study are to elucidate the physical mechanisms by which acoustic waves are generated, to clarify the roles of the fluctuating Reynolds stress and the viscous stress in the presence of a solid surface, and to determine the relative efficiency as a noise source of the various transition stages. In particular, we will examine the acoustic characteristics and directivity associated with three-dimensional instability waves, the detached high-shear layer, and turbulent spots following a laminar breakdown. Additionally, attention will be paid to the unsteady surface pressures during the transition, which provide a source of flow noise as well as a forcing function for wall vibration in both aeronautical and marine applications. DIRECT SIMULATION OF ISOTHERMAL-WALL SUPERSONIC CHANNEL FLOW c02
Gary N. Coleman *In its* Annual Research Briefs, 1993 Dec. 1993 p 313-328 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

The motivation for this work is the fact that in turbulent flows where compressibility effects are important, they are often poorly understood. A few examples of such flows are those associated with astrophysical phenomena and those found in combustion chambers, supersonic diffusers and nozzles, and over high-speed airfoils. For this project, we are primarily interested in compressibility effects near solid surfaces. Our main objective is an improved understanding of the fundamentals of compressible wall-bounded turbulence, which can in turn be used to cast light upon modeling concepts such as the Morkovin hypothesis and the Van Driest transformation. To this end, we have performed a direct numerical simulation (DNS) study of supersonic turbulent flow in a plane channel with constant-temperature walls. All of the relevant spatial and temporal scales are resolved so that no sub grid scale or turbulence model is necessary. The channel geometry was chosen so that finite Mach number effects can be isolated by comparing the present results to well established incompressible channel data. Here the fluid is assumed to be an ideal gas with constant specific heats, constant Prandtl number, and power-law temperature-dependent viscosity. Isothermal-wall boundary conditions are imposed so that a statistically stationary state may be obtained. The flow is driven by a uniform (in space) body force (rather than a mean pressure gradient) to preserve stream wise homogeneity, with the body force defined so that the total mass flux is constant. EFFECTS OF SHOCK STRENGTH ON SHOCK TURBULENCE INTERACTION
Sangsan Lee *In its* Annual Research Briefs, 1993 Dec. 1993 p 329-345 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

Direct numerical simulation (DNS) and linear analysis (LIA) of isotropic turbulence interacting with a shock wave are performed for several upstream shock normal Mach numbers (M(sub 1)). Turbulence kinetic energy (TKE) is amplified across the shock wave, but this amplification tends to saturate beyond M(sub 1) = 3.0. TKE amplification and Reynolds stress anisotropy obtained in DNS are consistent with LIA predictions. Rapid evolution of TKE immediate downstream of the shock wave persists for all shock strengths and is attributed to the transfer between kinetic and potential modes of turbulence energy through acoustic fluctuations. Changes in energy spectra and various length scales across the shock wave are predicted by LIA, which is consistent with DNS results. Most turbulence length scales decrease across the shock. Dissipation length scale (rho-bar q(exp 3) / epsilon), however, increases slightly for shock waves with M(sub 1) less than 1.65. Fluctuations in thermodynamic variables behind the shock wave stay nearly isentropic for M(sub 1) less than 1.2 and deviate significantly from isentropy for the stronger shock waves due to large entropy fluctuation generated through the interaction. LOCAL ISOTROPY IN DISTORTED TURBULENT BOUNDARY LAYERS AT HIGH REYNOLDS NUMBER
Seyed G. Saddoughi *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 347-363 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

This is a report on the continuation of our experimental investigations of the hypothesis of local isotropy in shear flows. This hypothesis, which states that at sufficiently high Reynolds numbers the small-scale structures of turbulent motions are independent of large-scale structures and mean deformations, has been used in theoretical studies of turbulence and computational methods such as large-eddy simulation. Since Kolmogorov proposed his theory, there have been many experiments, conducted in wakes, jets, mixing layers, a tidal channel, and atmospheric and laboratory boundary layers, in which attempts have been made to verify - or refute - the local-isotropy hypothesis. However, a review of the literature over the last five decades indicated that, despite all these experiments in shear flows, there was no consensus in the scientific community regarding this hypothesis, and, therefore, it seemed worthwhile to undertake a fresh experimental investigation into this question. COMPUTATION OF LARGE-SCALE STATISTICS IN DECAYING ISOTROPIC TURBULENCE
Jeffrey R. Chasnov *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 365-371 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

We have performed large-eddy simulations of decaying isotropic turbulence to test the prediction of self-similar decay of the energy spectrum and to compute the decay exponents of the kinetic energy. In general, good agreement between the simulation results and the assumption of self-similarity were obtained. However, the statistics of the simulations were insufficient to compute the value of gamma which corrects the decay exponent when the spectrum follows a k(exp 4) wave number behavior near k = 0. To obtain good statistics, it was found necessary to average over a large ensemble of turbulent flows. Derived from text

ON THE DYNAMICS OF APPROXIMATING SCHEMES FOR DISSIPATIVE NONLINEAR EQUATIONS
Donald A. Jones *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 373-386 (For primary document see N94-24138 06-34)
Avail: CASI HC A03/MF A04

Since one can rarely write down the analytical solutions to nonlinear dissipative partial differential equations (PDE's), it is important to understand whether, and in what sense, the behavior of approximating schemes to these equations reflects the true dynamics of the original equations. Further, because standard error estimates between approximations of the true solutions coming from spectral methods - finite difference or finite element schemes, for example - and the exact solutions grow exponentially in time, this analysis provides little value in understanding the infinite time behavior of a given approximating scheme. The notion of the global attractor has been useful in quantifying the infinite time behavior of dissipative PDEs, such as the Navier-Stokes equations. Loosely speaking, the global attractor is all that remains of a sufficiently large bounded set in phase space mapped infinitely forward in time under the evolution of the PDE. Though the attractor has been shown to have some nice properties - it is compact, connected, and finite dimensional, for example - it is in general quite complicated. Nevertheless, the global attractor gives a way to understand how the infinite time behavior of approximating schemes such as the ones coming from a finite difference, finite element, or spectral method relates to that of the original PDE. Indeed, one can often show that such approximations also have a global attractor. We therefore only need to understand how the structure of the attractor for the PDE behaves under approximation. This is by no means a trivial task. Several interesting results have been obtained in this direction. However, we will not go into the details. We mention here that approximations generally lose information about the system no matter how accurate they are. There are examples that show certain parts of the attractor may be lost by arbitrary small perturbations of the original equations. Derived from text

TENSORAL FOR POST-PROCESSING USERS AND SIMULATION AUTHORS **c61**
Eliot Dresselhaus *In* Stanford Univ., Annual Research Briefs, 1993 Dec. 1993 p 387-394 (For primary document see N94-24138 06-34)
Avail: CASI HC A02/MF A04

The CTR post-processing effort aims to make turbulence simulations and data more readily and usefully available to the research and industrial communities. The Tensoral language, which provides the foundation for this effort, is introduced here in the form of a user's guide. The Tensoral user's guide is presented in two main sections. Section one acts as a general introduction and guides database users who wish to post-process simulation databases. Section two gives a brief description of how database authors and other advanced users can make simulation codes and/or the databases they generate available to the user community via Tensoral database back ends. The two-part structure of this document conforms to the two-level design structure of the Tensoral language. Tensoral has been designed to be a general computer language for performing tensor calculus and statistics on numerical data. Tensoral's generality allows it to be used for stand-alone native coding of high-level post-processing tasks (as described in section one of this guide). At the same time, Tensoral's specialization to a minute task (namely, to numerical tensor calculus and statistics) allows it to be easily embedded into applications written partly in Tensoral and partly in other computer languages (here, C and Vectoral). Embedded Tensoral, aimed at advanced users for more general coding (e.g. of efficient simulations, for interfacing with pre-existing software, for visualization, etc.), is described in section two of this guide. EXPERIMENTAL STUDY OF A TURBULENT BOUNDARY LAYER IN PRESENCE OF EXTERNAL MANIPULATORS OF NACA 0009 PROFILE IN THE TRANSONIC REGIME M.S. Thesis [ETUDE EXPERIMENTALE D'UNE COUCHE LIMITE TURBULENTE EN PRESENCE DE MANIPULATEURS EXTERNES DE PROFIL NACA 0009 EN REGIME TRANSSONIQUE]
Diane Poirier May 1990 293 p In FRENCH
(ISBN-0-315-57633-2; CTN-94-60874) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An experimental study was conducted to determine the effectiveness of manipulators of external-type turbulence on the reduction of wall drag in a turbulent boundary layer in the transonic regime. The manipulators used, NACA 0009 thin profile type, have an aerodynamic behavior inappropriate for this type of application. Flow visualizations show that the flow on the manipulator is complex, with regions of separation, as well as recirculation, and that the wake of the manipulator is sometimes very unstable. Some of such behavior may be the origin of the high levels of drag encountered and adversely affects the effectiveness of this method in the sense of net balance. The analysis of the average velocity profiles, downstream of the single manipulator, does not permit reaching definitive quantitative conclusions since it leads to abnormally high reductions of the coefficient of wall drag, due apparently to the presence of a longitudinal pressure gradient which was not considered in the equation of motion. CENTER FOR MODELING OF TURBULENCE AND TRANSITION: RESEARCH BRIEFS, 1993 Annual Report, Jun. 1992 - Jul. 1993
William W. Liou, ed. Jan. 1994 249 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106383; ICOMP-93-44; E-8202; NAS 1.15:106383; CMOTT-93-16) Avail: CASI HC A11/MF A03

This research brief contains the progress reports of the research staff of the Center for Modeling of Turbulence and Transition (CMOTT) from June 1992 to July 1993. It is also an annual report to the Institute for Computational Mechanics in Propulsion located at Ohio Aerospace Institute and NASA Lewis Research Center. The main objectives of the research activities at CMOTT are to develop, validate, and implement turbulence and transition models for flows of interest in propulsion systems. Currently, our research covers eddy viscosity one- and two-equation models, Reynolds-stress algebraic equation models, Reynolds-stress transport equation models, nonequilibrium multiple-scale models, bypass transition models, joint scalar probability density function models, and Renormalization Group Theory and Direct Interaction Approximation methods. Some numerical simulations (LES and DNS) have also been carried out to support the development of turbulence modeling. Last year was CMOTT's third year in operation. During this period, in addition to the above mentioned research, CMOTT has also hosted the following programs: an eighteen-hour short course on 'Turbulence--Fundamentals and Computational Modeling (Part I)' given by CMOTT at the NASA Lewis Research Center; a productive summer visitor research program that has generated many encouraging results; collaborative programs with industry customers to help improve their turbulent flow calculations for propulsion system designs; a biweekly CMOTT seminar series with speakers from within and without the NASA Lewis Research Center including foreign speakers. In addition, CMOTT members have been actively involved in the national and international turbulence research activities. The current CMOTT roster and organization are listed in Appendix A. Listed in Appendix B are the abstracts of the biweekly CMOTT seminar. Appendix C lists the papers contributed by CMOTT members. Author (revised)

THE RADIATED NOISE FROM ISOTROPIC TURBULENCE REVISITED Final Report
Geoffrey M. Lilley Dec. 1993 56 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191547; ICASE-93-75; NAS 1.26:191547) Avail: CASI HC A04/MF A01

The noise radiated from isotropic turbulence at low Mach numbers and high Reynolds numbers, as derived by Proudman (1952), was the first application of Lighthill's Theory of Aerodynamic Noise to a complete flow field. The theory presented by Proudman involves the assumption of the neglect of retarded time differences and so replaces the second-order retarded-time and space covariance of Lighthill's stress tensor, Tij, and in particular its second time derivative, by the equivalent simultaneous covariance. This assumption is a valid approximation in the derivation of the second partial derivative of Tij/derivative of t exp 2 covariance at low Mach numbers, but is not justified when that covariance is reduced to the sum of products of the time derivatives of equivalent second-order velocity covariances as required when Gaussian statistics are assumed. The present paper removes these assumptions and finds that although the changes in the analysis are substantial, the change in the numerical result for the total acoustic power is small. The present paper also considers an alternative analysis which does not neglect retarded times. It makes use of the Lighthill relationship, whereby the fourth-order Tij retarded-time covariance is evaluated from the square of similar second order covariance, which is assumed known. In this derivation, no statistical assumptions are involved. This result, using distributions for the second-order space-time velocity squared covariance based on the Direct Numerical Simulation (DNS) results of both Sarkar and Hussaini(1993) and Dubois(1993), is compared with the re-evaluation of Proudman's original model. These results are then compared with the sound power derived from a phenomenological model based on simple approximations to the retarded-time/space covariance of Txx. Finally, the recent numerical solutions of Sarkar and Hussaini(1993) for the acoustic power are compared with the results obtained from the analytic solutions. Author (revised)

WORKSHOP ON COMPUTATIONAL TURBULENCE MODELING

A. Shabbir, comp., T.-H. Shih, comp., and L. A. Povinelli, comp. Jan. 1994 419 p Workshop held in Cleveland, OH, 15-16 Sep. 1993; sponsored by Institute for Computational Mechanics in Propulsion and Center for Modeling of Turbulence and Transition
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-CP-10130; ICOMP-93-46; E-8201; NAS 1.55:10130; CMOTT-93-17)
Avail: CASI HC A18/MF A04

The purpose of this meeting was to discuss the current status and future development of turbulence modeling in computational fluid dynamics for aerospace propulsion systems. Various turbulence models have been developed and applied to different turbulent flows over the past several decades and it is becoming more and more urgent to assess their performance in various complex situations. In order to help users in selecting and implementing appropriate models in their engineering calculations, it is important to identify the capabilities as well as the deficiencies of these models. This also benefits turbulence modelers by permitting them to further improve upon the existing models. This workshop was designed for exchanging ideas and enhancing collaboration between different groups in the Lewis community who are using turbulence models in propulsion related CFD. In this respect this workshop will help the Lewis goal of excelling in propulsion related research. This meeting had seven sessions for presentations and one panel discussion over a period of two days. Each presentation session was assigned to one or two branches (or groups) to present their turbulence related research work. Each group was asked to address at least the following points: current status of turbulence model applications and developments in the research; progress and existing problems; and requests about turbulence modeling. The panel discussion session was designed for organizing committee members to answer management and technical questions from the audience and to make concluding remarks. Author (revised)

STAGNATION REGION HEAT TRANSFER: THE INFLUENCE OF TURBULENCE PARAMETERS, REYNOLDS NUMBER AND BODY SHAPE
G. James VanFossen and Robert J. Simoneau Feb. 1994 17 p Prepared for presentation at the 6th AIAA/ASME Thermophysics and Heat Transfer Conference, Colorado Springs, CO, 20-23 Jun. 1994; sponsored by AIAA, and ASME
(RTOP 505-62-52)
(NASA-TM-106504; E-8534; NAS 1.15:106504) Avail: CASI HC A03/MF A01

The effect of velocity gradient on stagnation region heat transfer augmentation by free stream turbulence was investigated. Heat transfer was measured in the stagnation region of four models with elliptical leading edges with ratios of major to minor axes of 1:1, 1.5:1, 2.25:1, and 3:1. Four geometrically similar, square bar, square mesh, biplane grids were used to generate free stream turbulence with different intensities and length. Heat transfer measurements were made for the following ranges of parameters: Reynolds number, based on leading edge diameter, 37,000 to 228,000; dimensionless leading edge velocity gradient, 1.20 to 1.80; turbulence intensity, 1.1 to 15.9%; and length scale to leading edge diameter ratio, 0.05 to 0.30. Stagnation point heat transfer augmentation by free stream turbulence can be predicted using a modified version of a previously developed correlation for a circular leading edge. Heat transfer augmentation was independent of body shape at the stagnation point. The heat transfer distribution down-stream from the stagnation point can be predicted using the normalized laminar heat transfer distribution. Author

THERMAL-FLUID ANALYSIS OF THE FILL AND DRAIN OPERATIONS OF A CRYROGENIC FUEL TANK
Craig A. Stephens (Planning Research Corp., Edwards, CA.), Gregory J. Hanna (Hanna Technology Resources, Boulder, CO.), and Leslie Gong Washington Dec. 1993 20 p Presented at the SEM Structural Testing Technology at High Temperature 2 Conference, Ojai, CA, 8-10 Nov. 1993
(RTOP 505-70-63)
(NASA-TM-104273; H-1961; NAS 1.15:104273) Avail: CASI HC A03/MF A01

The Generic Research Cryogenic Tank was designed to establish techniques for testing and analyzing the behavior of reusable fuel tank structures subjected to cryogenic fuels and aerodynamic heating. The Generic Research Cryogenic Tank tests will consist of filling a pressure vessel to a prescribed fill level, waiting for steady-state conditions, then draining the liquid while heating the external surface to simulate the thermal environment associated with hypersonic flight. Initial tests of the Generic Research Cryogenic Tank will use liquid nitrogen with future tests requiring liquid hydrogen. Two-dimensional finite-difference thermal-fluid models were developed for analyzing the behavior of the Generic Research Cryogenic Tank during fill and drain operations. The development and results of the two-dimensional fill and drain models, using liquid nitrogen, are provided, along with results and discussion on extrapolating the model results to the operation of the full-size Generic Research Cryogenic Tank. These numerical models provided a means to predict the behavior of the Generic Research Cryogenic Tank during testing and to define the requirements for the Generic Research Cryogenic Tank support systems such as vent, drain, pressurization, and instrumentation systems. In addition, the fill model provided insight into the unexpected role of circumferential conduction in cooling the Generic Research Cryogenic Tank pressure vessel during fill operations. Author

THE ACOUSTIC AND INSTABILITY WAVES OF JETS CONFINED INSIDE AN ACOUSTICALLY LINED RECTANGULAR DUCT Final Report
Fang Q. Hu (Old Dominion Univ., Norfolk, VA.) Dec. 1993 30 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191586; NAS 1.26:191586; ICASE-93-98) Avail: CASI HC A03/MF A01

An analysis of linear wave modes associated with supersonic jets confined inside an acoustically lined rectangular duct is presented. Mathematical formulations are given for the vortex-sheet model and continuous mean flow model of the jet flow profiles. Detailed dispersion relations of these waves in a two-dimensional confined jet as well as an unconfined free jet are computed. Effects of the confining duct and the liners on the jet instability and acoustic waves are studied numerically. It is found that the effect of the liners is to attenuate waves that have supersonic phase velocities relative to the ambient flow. Numerical results also show that the growth rates of the instability waves could be reduced significantly by the use of liners. In addition, it is found that the upstream propagating neutral waves of an unconfined jet could become attenuated when the jet is confined. Author

RESPONSES OF A FINITE BAFFLED PLATE SUBJECT TO TURBULENT AND MEAN FLOW EXCITATIONS Final Report
Sean F. Wu (Wayne State Univ., Detroit, MI.) and Lucio Maestrello Dec. 1993 28 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191570; NAS 1.26:191570; ICASE-93-89) Avail: CASI HC A03/MF A01

Formulations for predicting dynamic and acoustic responses of a finite plate flush-mounted on an infinite baffle subject to turbulent and mean flow excitations are presented. In deriving these formulations, the effects of stretching due to in-plane force and coupling between structural vibration and acoustic radiation are taken into account. The resulting equation governing plate vibration contains cubic nonlinearities. To obtain an approximate solution, the plate flexural displacement is expanded into orthogonal base functions. The unknown coefficients associated with base functions are determined by solving a set of coupled nonlinear integral equations using Galerkin's method. A stability analysis is given using the basic existence-uniqueness theorem. In particular, stable conditions for a linearized system are obtained using the Routh algorithm. It is shown that structural instabilities can be induced by fluid loading and mean flow. Two unstable mechanisms are found to be attributable to added damping and stiffness due to acoustic radiation. The effect of added damping increases linearly, while that of added stiffness increases quadratically with the Mach number of mean flow. Finally, the cross-power spectral density functions of plate flexural vibration and radiated acoustic pressure are derived and expressed in terms of the cross-power spectral density function of turbulent flow. IMPLEMENTATION OF THE BALDWIN-BARTH TURBULENCE MODEL INTO THE ZETA CODE AND ITS DIAGNOSIS M.S. Thesis
Scott L. Low 16 Jun. 1993 112 p Original contains color illustrations
(Contract NCA2-722)
(NASA-CR-194795; NAS 1.26:194795) Copyright Avail: CASI HC A06/MF A02; 14 functional color pages

The Baldwin-Barth turbulence model was implemented into Zeta, a time-accurate, zonal, integro-differential code for incompressible laminar and turbulent flows. The implementation procedure is patterned after the model subroutine in ARC2D. The results of ZETA with the Baldwin-Barth turbulence model were compared with experimental data, with ZETA using Baldwin-Lomax model, and with ARC2D using the Baldwin-Barth model. The Baldwin-Barth model subroutine was tested by inputting an ARC2D velocity solution of an NACA-0012 airfoil at R(sub e) = 3.9 x 10(exp 6) and alpha = 5 deg. The resultant turbulent viscosity and Reynolds stresses compared favorably with the original data. For the same grid having grid points inside the laminar sublayer, which is necessary due to the one-equation nature of the model, ZETA however predicts early separation. It was found that the current ZETA has problem with such a fine grid. Further work is in progress to solve this problem. Author

SOLUTION OF THE DISCRETIZED INCOMPRESSIBLE NAVIER-STOKES EQUATIONS WITH ITERATIVE METHODS
C. Vuik 1993 14 p Conference on the 26th ISATA, Supercomputing Applications in the Automative Industries held in Aachen, Germany, Sep. 1993 See also PB91-217687
(PB94-118635; Rept-93-54) Copyright Avail: CASI HC A03/MF A01

We describe a numerical solution method for the incompressible Navier-Stokes equations in complex geometries. We use a finite volume technique in combination with boundary-fitted coordinates. The physical domain is mapped onto a computational domain consisting of a number of regular blocks. We restrict ourselves to the one block case. In these problems it is important to obtain fast iterative methods to solve the discretized equations. This is easier using a finite volume technique instead of a finite element technique. Finally, the structured grid enables us to develop a fast implementation of the methods on vector computers. NTIS

A TWO-DIMENSIONAL DISPERSION MODULE FOR THE TOUGH2 SIMULATOR
C. M. Oldenburg and K. Pruess Sep. 1993 64 p
(Contract DE-AC03-76SF-00098)
(DE94-002262; LBL-32505) Avail: CASI HC A04/MF A01

A standard model for hydrodynamic dispersion has been added to TOUGH2--the dispersion model, intended for use with the EOS7 fluid properties module, accounts for the effects of hydrodynamic dispersion and molecular diffusion in two-dimensional rectangular domains. Because the model requires Darcy velocity and species concentration gradient vectors at all connections, known vector components (perpendicular to the grid block interfaces) from neighboring connections are interpolated to form the unknown components (parallel to the grid block interfaces) at each connection. Thus, the dispersive fluxes depend not only on the primary variables of the two connected grid blocks but on all p variables of the six neighbor grid blocks of each interface. This gives rise to added terms in the Jacobian matrix relative to standard TOUGH2 where fluxes depend only on primary variables in the two connected grid blocks. For flexibility in implementing boundary conditions, the model allows the user to define a flow domain that is a subset of the calculation domain. The PARAM and SELEC blocks of the TOUGH2 input file are used to specify parameters and boundary condition options for the dispersion module. The dispersion module has been verified by comparing computed results to analytical solutions. As an introduction to applications, we demonstrate the solution of a difficult two dimensional flow problem with variable salinity and strong coupling between dispersive and advective flow. DOE

FREE-SURFACE/VORTICITY INTERACTION M.S. Thesis
John B. Carroll Sep. 1993 57 p
(AD-A273263) Avail: CASI HC A04/MF A01

The unsteady flow phenomena resulting from the interaction of wakes and vortices with the free surface are of particular importance in naval hydrodynamics. Ship and submarine wakes produce a three-dimensional complex signature, comprised of a narrow dark band bordered by two bright lines in synthetic-aperture-radar (SAR) images. The dark band signifies the suppression of waves at the Bragg frequency as a consequence of the interaction between the free surface and the imposed vorticity. In the present investigation, the vorticity field is provided by a single tip vortex generated by an airfoil. The results, obtained with an LDV, have shown that the free surface redistributes part or all of the normal turbulent kinetic energy into streamwise and spanwise components. The turbulent kinetic energy first decreases sharply with increasing vertical distance from the vortex and then remains nearly constant within a thin layer below the 'roughened' free surface. The results explain the longevity of the structures and lend further credence to the simulation of near-surface structures via vortex- or contour-dynamics. DTIC

HEAT TRANSFER AND FLOW STRUCTURE IN END-WALL BOUNDARY LAYERS Final Report, 15 Mar. 1991 - 15 Mar. 1993
C. R. Smith and J. D. Walker 11 Aug. 1993 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0218-91)
(AD-A273470; AFOSR-93-0875TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Research progress is described for a combined analytical/experimental program examining the flow structure and resultant surface heat transfer in end-wall boundary layers (e.g. wing-body. type junctures). Emphasis is placed on flow structure development and correlation of vortex-induced surface interactions with transient, local surface heat transfer. Analytically, numerical studies using an impulsively-started approach flow have documented the flow development and surface heat transfer on the symmetry plane for several end-wall flows; highly unsteady vortex formation and ejection are observed, with concomitant sharp, transient variations in surface heat transfer. Analysis of the complete three-dimensional behavior indicates the presence of strong interactions between the end-wall (surface) and the side-wall (bluff-body) boundary layers. Experimentally, a constant heat flux test system has been developed and instrumented for surface temperature detection using temperature-sensitive liquid crystals and color computer-image analysis; tests indicate dramatic effects of transient end-wall vortices on surface heat transfer, confirming the analytical results. A systematic visualization study indicates a very strong influence of the junction-induced pressure gradient on the approach boundary layer in promoting the unsteady vortex formation processes in the end-wall region. CARRYING THE MASS FLUX TERMS EXACTLY IN THE FIRST AND SECOND MOMENT EQUATIONS OF COMPRESSIBLE TURBULENCE Final Report
J. R. Ristorcelli Nov. 1993 10 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191568; NAS 1.26:191568; ICASE-93-87) Avail: CASI HC A02/MF A01

In compressible turbulence models, it is assumed that the Favre-mean velocities are suitable approximations to the Reynolds-mean velocities in order to close unknown terms. This neglects, in the mean momentum and energy equations, the contribution to the stress and work terms by the mean of the fluctuating Favre velocity, a quantity proportional to the turbulent mass flux. As the stress and work terms do not introduce any new unknown correlations requiring closure in either k-epsilon or Reynolds stress closures and because the exact form of the terms can, with little additional work, be carried there is no need to make any modeling assumptions. In the Reynolds stress equations the viscous terms appear naturally in Reynolds variables while the problem is posed in Favre variables. In the process of splitting the viscous terms into the viscous transport terms, carried in Favre variables, and the dissipation terms, carried in Reynolds variables, important contributions from the mass flux appear. The accurate accounting of these terms is important for any consistent near wall modeling and the retention of the mass flux terms is important in complex compressible turbulent flows. A VORTICITY DYNAMICS BASED MODEL FOR THE TURBULENT DISSIPATION: MODEL DEVELOPMENT AND VALIDATION
Tsan-Hsing Shih, William W. Liou, Aamir Shabbir, Zhigang Yang, and Jian Zhu Jan. 1994 31 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106177; ICOMP-93-20; CMOTT-93-08; E-7877; NAS 1.15:106177) Avail: CASI HC A03/MF A01

A new model dissipation rate equation is proposed based on the dynamic equation of the mean-square vorticity fluctuation for large Reynolds number turbulence. The advantage of working with the vorticity fluctuation equation is that the physical meanings of the terms in this equation are more clear than those in the dissipation rate equation. Hence, the model development based on the vorticity fluctuation equation is more straightforward. The resulting form of the model equation is consistent with the spectral energy cascade analysis introduced by Lumley. The proposed model dissipation rate equation is numerically well behaved and can be applied to any level of turbulence modeling. It is applied to a realizable eddy viscosity model. Flows that are examined include: rotating homogeneous shear flows; free shear flows; a channel flow and flat plate boundary layers with and without pressure gradients; and backward facing step separated flows. In most cases, the present model predictions show considerable improvement over the standard kappa-epsilon model. Author (revised)

RELATIONSHIP BETWEEN TRANSITION AND MODES OF INSTABILITY IN SUPERSONIC BOUNDARY LAYERS
Jamal A. Masad Dec. 1993 26 p
(Contract NAS1-19299; RTOP 537-03-23-03)
(NASA-CR-4562; NAS 1.26:4562) Avail: CASI HC A03/MF A01

The relationship between the predicted transition location and the first and second modes of instability in two-dimensional supersonic boundary-layer flow on a flat plate is examined. Linear stability theory and the N-factor criterion are used to predict transition location. The effect of heat transfer is also studied; the results demonstrate that the transition reversal phenomenon can be explained by the opposite effect of cooling on the first and second modes of instability. Compressibility of destabilizing at free-stream Mach numbers of 2 to 3.5. The predicted transition location is due to the oblique first modes of instability, up to free-stream Mach numbers between 6 and 6.5. At higher Mach numbers, the predicted transition location is due to a combination of two-dimensional first and second modes of instability. Author

BEM SOLUTION FOR THE SIMULATION OF AXISYMMETRIC VISCOUS SINTERING
G. A. L. vandeVorst Nov. 1992 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-237717; RANA-92-16) Avail: CASI HC A03

A numerical method to simulate particular axisymmetric viscous sintering problems is presented. In these problems the material transport is modeled as a viscous incompressible Newtonian volume flow driven solely by surface tension. The numerical simulation is carried out by solving the governing Stokes equations for a fixed domain through a Boundary Element Method (BEM). The resulting velocity field then determines an approximate geometry at a next time level by employing a variable step, variable order Backward Differences Formulas (BDF) method. This numerical algorithm is demonstrated for the sintering of two equal spheres. NTIS

HYPULSE COMBUSTOR ANALYSIS
O. F. Rizkalla Dec. 1993 47 p
(Contract NAS1-18450; RTOP 763-23-21)
(NASA-CR-191579; TR-352; NAS 1.26:191579) Avail: CASI HC A03/MF A01

The analysis of selected data from tests of unit fuel injectors in a generic scramjet combustor model is presented. The tests were conducted in the NASA HYPULSE expansion tube at conditions typical of flight at Mach 13.5 and 17. The analysis used a three-stream tube method, with finite-rate chemistry, in which the fuel, test gas, and mixing/combustive streams were treated independently but with the same static pressure. Performance of three candidate fuel injectors is examined based on deduced mixing and combustion efficiencies. Author

INTERACTIVE CONTROL IN TURBULENT SHEAR LAYERS Final Report, Feb. 1990 - Jan. 1993
Candace E. Wark and Hassan M. Nagib 11 Oct. 1993 30 p
(Grant AF-AFOSR-0171-90)
(AD-A273544; AFOSR-93-0876TR) Avail: CASI HC A03/MF A01

Investigations of wall-bounded shear flow at IIT have been primarily focused on the following issues: (1) inner- and outer-layer effects on the dynamics of a turbulent boundary layer (TBL), (2) a PIV study of fully developed turbulent pipe flow, (3) the effects of intermittency on the wall-layer dynamics, and (4) the visualization of active events near the wall. The motivations behind these investigations are to understand the Reynolds number sensitivity and relative importance of the different scales of motion, with regard to the dynamics of turbulent wall-bounded flow and to document and study the instantaneous structure of the flow vis-a-vis the numerous coherent structure studies of the last two decades. A temporal filtering scheme was devised to separate the contribution of the different scales of motion to the u' signal and the Reynolds stress in the buffer and logarithmic region. Also, using PIV, instantaneous large-scale structures were observed, which are not seen in low Reynolds number direct numerical simulations of bounded turbulent shear flows. The analysis of flow visualization records of active events in a TBL was performed in the frame of a conjectured model that is based on Theodorsen's original hairpin vortex flow module. Information on the character, size, location, intensity and duration of the events was documented and tabulated. DTIC

FLOW AND TEMPERATURE DISTRIBUTION IN A NATURALLY STRATIFIED THERMAL STORAGE TANK Final Report
Maurice W. Wildin and Chang W. Sohn Oct. 1993 34 p
(AD-A273511; USACERL-TR-FE-94/01) Avail: CASI HC A03/MF A01

Thermal energy storage for building and process cooling is employed in two principal forms: sensible and latent. Each form has its advantages and disadvantages. Currently, water is the most frequently used storage medium for cooling, with the solid/liquid phase change being used for latent storage and chilled liquid water used for sensible storage. This report deals exclusively with sensible storage in water. Researchers studied the effects of mixing on the creation and maintenance of a thermocline during the charging of a thermal storage tank for cooling and the effects of momentum of inlet fluid and buoyancy due to temperature differences on the creation and maintenance of thermoclines. From the design point of view, the inlet parameters and their ranges for optimal performance of a stratified thermal storage tank have been more clearly delineated. The upper limit of the range of the Reynolds number for optimal stratified chilled water storage tank performance appears to be between 400 and 600. The upper limit of the densimetric Froude number range was determined in a previous study, and is about 2. DTIC

NUMERICAL SOLUTIONS OF THE COMPLETE NAVIER-STOKES EQUATIONS Progress Report No. 24, 1 Jul. - 31 Dec. 1993

H. A. Hassan 31 Dec. 1993 10 p
(Grant NAG1-244)
(NASA-CR-194780; NAS 1.26:194780) Avail: CASI HC A02/MF A01

The objective of this study is to compare the use of assumed pdf (probability density function) approaches for modeling supersonic turbulent reacting flowfields with the more elaborate approach where the pdf evolution equation is solved. Assumed pdf approaches for averaging the chemical source terms require modest increases in CPU time typically of the order of 20 percent above treating the source terms as 'laminar.' However, it is difficult to assume a form for these pdf's a priori that correctly mimics the behavior of the actual pdf governing the flow. Solving the evolution equation for the pdf is a theoretically sound approach, but because of the large dimensionality of this function, its solution requires a Monte Carlo method which is computationally expensive and slow to coverage. Preliminary results show both pdf approaches to yield similar solutions for the mean flow variables. Author (revised)

(Contract NCC1-22)
(NASA-CR-194765; NAS 1.26:194765) Avail: CASI HC A03/MF A01

Two papers are included in this progress report. In the first, the compressible Navier-Stokes equations have been used to compute leading edge receptivity of boundary layers over parabolic cylinders. Natural receptivity at the leading edge was simulated and Tollmien-Schlichting waves were observed to develop in response to an acoustic disturbance, applied through the farfield boundary conditions. To facilitate comparison with previous work, all computations were carried out at a free stream Mach number of 0.3. The spatial and temporal behavior of the flowfields are calculated through the use of finite volume algorithms and Runge-Kutta integration. The results are dominated by strong decay of the Tollmien-Schlichting wave due to the presence of the mean flow favorable pressure gradient. The effects of numerical dissipation, forcing frequency, and nose radius are studied. The Strouhal number is shown to have the greatest effect on the unsteady results. In the second paper, a transition model for low-speed flows, previously developed by Young et al., which incorporates first-mode (Tollmien-Schlichting) disturbance information from linear stability theory has been extended to high-speed flow by incorporating the effects of second mode disturbances. The transition model is incorporated into a Reynolds-averaged Navier-Stokes solver with a one-equation turbulence model. Results using a variable turbulent Prandtl number approach demonstrate that the current model accurately reproduces available experimental data for first and second-mode dominated transitional flows. The performance of the present model shows significant improvement over previous transition modeling attempts. Author (revised)

VORTEX GENERATION AND WAVE-VORTEX INTERACTION OVER A CONCAVE PLATE WITH ROUGHNESS AND SUCTION Final Report

Fabio Bertolotti Dec. 1993 42 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191589; ICASE-93-101; NAS 1.26:191589) Avail: CASI HC A03/MF A01

The generation and amplification of vortices by surface homogeneities, both in the form of surface waviness and of wall-normal velocity, is investigated using the nonlinear parabolic stability equations. Transients and issues of algebraic growth are avoided through the use of a similarity solution as initial condition for the vortex. In the absence of curvature, the vortex decays as the square root of 1/x when flowing over streamwise aligned riblets of constant height, and grows as the square root of x when flowing over a corresponding streamwise aligned variation of blowing/suction transpiration velocity. However, in the presence of wall inhomogeneities having both streamwise and spanwise periodicity, the growth of the vortex can be much larger. In the presence of curvature, the vortex develops into a Gortler vortex. The 'direct' and 'indirect' interaction mechanisms possible in wave-vortex interaction are presented. The 'direct' interaction does not lead to strong resonance with the flow conditions investigated. The 'indirect' interaction leads to K-type transition. Author (revised)

DEVELOPMENT AND VALIDATION OF RNG METHODOLOGY FOR COMPRESSIBLE TURBULENCE Final Report, 1 Apr. 1989 - 31 Mar. 1993

G. E. Karniadakis and A. Smits Oct. 1993 5 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0261-90)
(AD-A273469; AFOSR-93-0868TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

All three different categories of tasks described in our AFOSR proposal (Grant 90-0261) were completed successfully: (1) Development of Renormalization Group theory (RNG) for compressible turbulence; (2) Design and measurements of a compressible boundary layer experiment, and (3) Development of spectral element algorithms for compressible flows. A brief summary follows. On the theoretical side first, the new results obtained for compressible turbulence are: (1) At the large scales the effective sound velocity in compressible turbulence is scale-dependent and obeys a universal equation of state; (2) The effective, scale-dependent Mach number based on the rms value of velocity approaches a fixed point corresponding to effectively subsonic flow; (3) The potential component of the velocity field (sound waves) does not alter the scaling of the energy spectrum of incompressible (rotational) component. This decoupling of events in rotational and compressibility effects suggests that most of the RNG modeling for incompressible flows is also valid for compressible flows as long as compressibility is taken into account. TURBULENCE MODELS AND REYNOLDS ANALOGY FOR TWO-DIMENSIONAL SUPERSONIC COMPRESSION RAMP FLOW

Chi R. Wang and Maleina C. Bidek (Cornell Univ., Ithaca, NY.) Jan. 1994 15 p Proposed for presentation at the 1994 Thermophysics and Heat

Transfer Conference, Colorado Springs, CO, 20-23 Jun. 1994; sponsored by ASME
(RTOP 505-62-52)
(NASA-TM-106474; E-8349; NAS 1.15:106474) Avail: CASI HC A03/MF A01

Results of the application of turbulence models and the Reynolds analogy to the Navier-Stokes computations of Mach 2.9 two-dimensional compression ramp flows are presented. The Baldwin-Lomax eddy viscosity model and the kappa-epsilon turbulence transport equations for the turbulent momentum flux modeling in the Navier-Stokes equations are studied. The Reynolds analogy for the turbulent heat flux modeling in the energy equation was also studied. The Navier-Stokes equations and the energy equation were numerically solved for the flow properties. The Reynolds shear stress, the skin friction factor, and the surface heat transfer rate were calculated and compared with their measurements. It was concluded that with a hybrid kappa-epsilon turbulence model for turbulence modeling, the present computations predicted the skin friction factors of the 8 deg and 16 deg compression ramp flows and with the turbulent Prandtl number Pr(sub t) = 0.93 and the ratio of the turbulent thermal and momentum transport coefficients mu(sub q)/mu(sub t) = 2/Prt, the present computations also predicted the surface heat transfer rates beneath the boundary layer flow of the 16 compression ramp. ACTIVE CONTROL OF OSCILLATORY LIFT FORCES ON A CIRCULAR CYLINDER Professional Paper

D. M. Ladd, D. S. Park, E. W. Hendricks, and N. S. Nosseir Aug. 1993 8 p
(AD-A273243) Avail: CASI HC A02/MF A01

The results of a computational and experimental study of feedback control of Karman vortex shedding behind a circular cylinder are presented. The experiments were performed in a nominally two dimensional flow around a 12.7 mm cylinder at Reynolds numbers up to 10,000. The computations utilized the two-dimensional Navier-Stokes equations at Reynolds numbers up to 100. In both experimental and numerical studies blowing and suction slots were used to control the vortex shedding. In the numerical study complete suppression of vortex shedding is achieved up to a Reynolds number Re = 80 (about 70% above the onset Reynolds number for vortex shedding). In the experimental study using the fluctuating lift force as feedback, about 50% suppression of the rms fluctuations has been achieved at a Reynolds number of approximately 10,000. DTIC

A CONTINUING SEARCH FOR A NEAR-PERFECT NUMERICAL FLUX SCHEME. PART 1: AUSM+

Meng-Sing Liou Mar. 1994 47 p Presented at the 5th International Symposium on Computational Fluid Dynamics, Sendai, Japan, 31 Aug. - 3 Sep. 1993
(RTOP 505-62-52)
(NASA-TM-106524; NAS 1.15:106524) Avail: CASI HC A03/MF A01

While enjoying demonstrated improvement in accuracy, efficiency, and robustness over existing schemes, the Advection Upstream Splitting Scheme (AUSM) was found to have some deficiencies in extreme cases. This recent progress towards improving the AUSM while retaining its advantageous features is described. The new scheme, termed AUSM+, features: unification of velocity and Mach number splitting; exact capture of a single stationary shock; and improvement in accuracy. A general construction of the AUSM+ scheme is layed out and then focus is on the analysis of the a scheme and its mathematical properties, heretofore unreported. Monotonicity and positivity are proved, and a CFL-like condition is given for first and second order schemes and for generalized curvilinear co-ordinates. Finally, results of numerical tests on many problems are given to confirm the capability and improvements on a variety of problems including those failed by prominent schemes. Author (revised)

MEASUREMENTS OF THE INFLUENCE OF INTEGRAL LENGTH SCALE ON STAGNATION REGION HEAT TRANSFER

G. James VanFossen and Chang Y. Ching (Syracuse Univ., NY.) Feb. 1994 22 p Proposed for presentation at the 5th Symposium on Transport Phenomena and Dynamics of Rotating Machinery, Kaanapali, HI, 8-11 May 1994; sponsored by the Pacific Center of Thermal Fluids Engineers
(RTOP 505-62-52)
(NASA-TM-106503; E-8532; NAS 1.15:106503) Avail: CASI HC A03/MF A01

The purpose was twofold: first, to determine if a length scale existed that would cause the greatest augmentation in stagnation region heat transfer for a given turbulence intensity and second, to develop a prediction tool for stagnation heat transfer in the presence of free stream turbulence. Toward this end, a model with a circular leading edge was fabricated with heat transfer gages in the stagnation region. The model was qualified in a low turbulence wind tunnel by comparing measurements with Frossling's solution for stagnation region heat transfer in a laminar free stream. Five turbulence generating grids were fabricated; four were square mesh, biplane grids made from square bars. Each had identical mesh to bar width ratio but different bar widths. The fifth grid was an array of fine parallel wires that were perpendicular to the axis of the cylindrical leading edge. Turbulence intensity and integral length scale were measured as a function of distance from the grids. Stagnation region heat transfer was measured at various distances downstream of each grid. Data were taken at cylinder Reynolds numbers ranging from 42,000 to 193,000. Turbulence intensities were in the range 1.1 to 15.9 percent while the ratio of integral length scale to cylinder diameter ranged from 0.05 to 0.30. Stagnation region heat transfer augmentation increased with decreasing length scale. An optimum scale was not found. A correlation was developed that fit heat transfer data for the square bar grids to within +4 percent. The data from the array of wires were not predicted by the correlation; augmentation was higher for this case indicating that the degree of isotropy in the turbulent flow field has a large effect on stagnation heat transfer. The data of other researchers are also compared with the correlation. Author (revised)

MECHANISMS OF DROPLET FORMATION Ph.D. Thesis

Gabriel Marinus Henr Meesters 1992 156 p
(ISBN-9-06-275765-0; ETN-94-95369) Avail: CASI HC A08/MF A02

The production of droplets in the micrometer range (1 to 5 micrometers) and the production of droplets a few decades larger (70 micrometer to 2 mm) is considered. In the production of droplets in the micrometer range, the liquids are dispersed with the help of a strong electric field. A phenomenon known as the Taylor cone is used for dispersion of the liquid. A Taylor cone is a conically shaped liquid droplet from whose apex small droplets are emitted. The phenomena of these liquid cones were also investigated. In producing droplets of diameter 70 micrometers to 2 mm, the liquid jet is forced to break up by applying a vibration onto the jet causing it to break up with the imposed frequency. Two different pieces of equipment were set up to investigate the break up behavior of liquids of low and high viscosity. Using this apparatus it was possible to define a particle size distribution over a wide range of diameters and to tailor it. ESA

FORCES ON AN OSCILLATING CYLINDER AND RELATED FLUID FLOW PHENOMENA Ph.D. Thesis

Andries Otter 1992 141 p Sponsored by Shell Research B.V.,

Netherlands Prepared in cooperation with Koninklijke/Shell Exploratie en Produktie Lab., Rijswijk, Netherlands nds Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISBN-9-09-005589-4; ETN-94-95377) Avail: Issuing Activity (European Space Agency (ESA))

The interaction between a circular cylinder oscillating along a diameter and the fluid surrounding it is studied. Attention is focused on the forces on the cylinder and the related fluid flow. The information will be applied to the design of certain offshore structures in deep waters. The flow phenomena associated with changes in the fluid induced forces, the transition and separation of the boundary layers, are reviewed. Laboratory experiments were carried out in which the in line and transverse forces on an oscillating cylinder were measured. Flow visualization experiments were performed to investigate the boundary layer stability and the boundary layer separation. In the review of the transition from laminar flow around a transversely oscillating cylinder, two different mechanisms are identified. It is explained that the same mechanisms are feasible in the case of a circular cylinder oscillating in rotation around its axis. It appears that an experiment on this configuration can be used in answering questions whether an interaction between the two mechanisms takes place and which are the consequences regarding the energy dissipation. The results of flow visualization experiments suggest that an interaction might occur. However, at the transition from laminar flow, no significant increase in the moment acting on the cylinder was found. ESA

THE HYDRODYNAMICS OF A MOVING FLUID-LIQUID CONTACT LINE Ph.D. Thesis
Antonius Johannus J. vanderZanden 1993 105 p
(ETN-94-95352) Avail: CASI HC A06/MF A02

The hydrodynamics associated with an advancing contact line, where a viscous liquid displaces a fluid with a negligible viscosity, is examined. A model is proposed which approximates the shape of an advancing meniscus in a tube or between parallel plates. Comparison of the predictions of the model with available numerical and experimental results provides an indication of its reliability. This model is applied to receding contact lines, where a viscous liquid is displaced by a fluid of negligible viscosity. The model is extended to examine moving liquid-liquid contact lines where the viscosity of neither fluid can be neglected. Experiments concerning the macroscopic shape of a meniscus in a tube and experiments which lay claim to be able to peep into the microscopic region close to the contact line not accessible with the naked eye are presented. ESA

DECAY OF SWIRL IN TURBULENT PIPE FLOWS Ph.D. Thesis
Rene Raymond Parchen 1993 149 p Sponsored by N.V. Dutch Gasunie, Netherlands
(ETN-94-95353) Avail: CASI HC A07/MF A02

An overview of the most widely used models of turbulence is given. The assumptions on which the models are based, starting from the most general closure scheme, the Reynolds stress model of turbulence, are described. To reveal some of the conceptual differences, the lower order schemes are derived from the more general schemes. Focus is on the modeling of flows with swirl. The prediction of axisymmetric swirling pipe flows is discussed. Employing existing turbulence closure schemes, simplified expressions for the turbulent stresses are derived. These simplified expressions allow the predicted effects of swirl on the turbulence as predicted by the various methods to be assessed. A detailed description of the consequences of the various assumptions on the prediction of the decay of swirl in turbulent pipe flows is given. The question of whether the assumption of axisymmetry in swirling pipe flows is valid is addressed. Numerical experiments are used to investigate the stability of the flow against nonaxisymmetric disturbances. The feasibility of numerical predictions of installation effects is discussed. ESA

Results of an investigation of the gas-liquid hydrodynamics of stirred tanks equipped with (profiled) axial flow impellers are reported. Three different flow regimes are distinguished. Only at low gas flow rates, when the gas-liquid flow is dominated by the liquid flow pattern as induced by the impeller, the flow pattern is steady state and the gas well dispersed. The mass transfer performance of these axial flow impellers was compared with that of disc turbines. Results of a computational study on the single phase flow with both radial pumping and axial pumping impellers are described. All computations were carried out with the fluid flow code FLUENT and the results were validated with experimental LDV (Laser Doppler Velocimetry) data. These single phase flow patterns serve as a basis for further study of the gas dispersion process in those hydrodynamic regimes where the flow is stable. The development of a predictive model for the gas-liquid flow in stirred vessels is considered. This model is incorporated in a code named GHOST (Gas Holdup Simulation Tool) which calculates local values of gas holdup, bubble size, and mass transfer rate on the basis of conservation equations and the single phase flow patterns computed earlier. The computational results are validated against experimental data gathered with optical fiber probes. A qualitative description of the spatial distribution of the gas holdup, the bubble size, and the mass transfer rate in stirred mixing vessels is given. This description results from using a combination of experimental data and GHOST results. Conclusions about further possible optimization of gassed stirred tanks are drawn. ESA

The effectiveness of riblet surfaces on the coherent motions in the near wall turbulent boundary layer was investigated. The effectiveness of drag reducing flat riblet surfaces during adverse pressure gradient flows was then examined. Some problems which are relevant for applications, like the angle between the flow and the riblets, the partial covering of a flat plate by riblets, and a ship model covered with riblets, were studied. ESA

ANALYSIS OF THE EFFECTS OF WAKE PASSAGE ON HEAT TRANSFER IN A LINEAR TURBINE CASCADE M.S. Thesis
Kevin S. Allen Dec. 1993 104 p
(AD-A273729; AFIT/GAE/ENY/93D-2) Avail: CASI HC A06/MF A02

The effect of wake passage on the heat transfer in a linear turbine cascade was investigated. The apparatus used was the Air-Force Institute of Technology Linear Turbine Cascade Test Facility (TCTF). The TCTF was fitted with a belt and pulley system to facilitate a series of translating bars. The bars, when passed upstream of the cascade, created a series of wakes. The parameters varied were freestream model Reynolds number and bar conditions, i.e., bars in, bars out, and bar passing frequency. One blade in the TCTF was instrumented to allow pressure and temperature measurements at discrete points on the blade's surface. From the pressure and temperature data the convective heat transfer coefficient at these discrete locations was calculated. Results were compared to previous TCTF heat transfer data, empirical solutions, and other wake passage experiments. For all tests with closely spaced bars, the effect of wake passing on the heat transfer of the blade was similar to the effect of grid-generated 10% freestream turbulence on the cascade. DTIC

The turbulent variations of the mass flow occurring in the mixing zone of a CO2 free jet in the air are calculated by Raman scattering. The calculation method consists in correlating photons given by the mass autocorrelation function. The mass of each component is obtained. The relationship between the amplitude of the mass flow turbulent variations and the measuring device pass band is shown. For a 64 channel photon correlator the analyzed band width was 2/3 octaves. The mean local mass around a cylindric-conic shape model tested in a supersonic wind tunnel was calculated. The wind tunnel flow was disturbed by a transversal methane flow. The calculated and the measured pressure fields at the wall are compared. It is shown that the resulting pressure forces can be calculated by the method. ESA

A program for calculating the load noise of a helicopter rotor was developed. The method, which requires the knowledge of the local blade load values, was extended to calculate the two dimensional flow around a foil in a field of vortices. A three dimensional method based on the lifting surface theory was developed to simulate the turbulent field developed by a pitch oscillating foil and interacting with another foil placed downstream. The calculated and the measured lift evolution values were compared. The flow velocity was measured by laser velocimetry and the configuration of the rotational flow field was obtained. ESA

AN ADAPTIVE STREAMLINE DIFFUSION FINITE ELEMENT METHOD FOR HYPERBOLIC SYSTEMS IN GAS DYNAMICS
Guohui Zhou Sep. 1992 141 p Sponsored by DFG Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Preprint-688; ETN-94-95084) Avail: CASI HC A07

The paintwise error analysis of the streamline diffusion method for two dimensional stationary problem with constant coefficients is extended to the time dependent problem. The purpose of the study is to justify a local mesh refinement strategy. The one dimensional Euler equations coming from the shock tube and Riemann's problem in gas dynamics are used. The gas is assumed to be at rest on both sides of the membrane, with pressure and density different on each side. The case where the problem is scalar and linear is discussed. Linear systems of hyperbolic type in one space variable and nonlinear scalar problems are studied. ESA

APPLICATIONS OF THE HOMOGENIZATION METHOD TO FLOW AND TRANSPORT IN POROUS MEDIA
Ulrich Hornung Sep. 1991 57 p
(Ber-9110; RB-5459; ETN-94-95086) Avail: CASI HC A04/MF A01

A survey of the homogenization method applied to porous media is presented. From a theoretical point of view the method studies partial differential equations with oscillatory coefficients, either periodically or stochastically. The homogenization of elliptic problems with periodic coefficients is discussed. Media with a spatially periodic array of obstacles are considered. It is shown that for time dependent problems the method of homogenization may lead to non-local equations. A formal derivation of Darcy's law is given. Two new problems are introduced: the problem of heterogeneous catalysis and the problem of reactive transport through an array of cells with semipermeable membranes. ESA

APPLICATION OF BODY FITTED-COORDINATES IN HEAT CONDUCTION PROBLEMS Ph.D. Thesis
Petrus Johannes Mari Sonnemans 1992 156 p
(ETN-94-95338) Avail: CASI HC A08/MF A02

A method to determine the 'effective' conductivity of a repetitive complex structure of a composite material is developed. The principles of heat transfer and some related numerical aspects are reviewed. The Taylor series method is presented as discretization technique to solve differential equations numerically. The discretization technique is generalized to solve two dimensional heat transport problems. The transport equation to be solved, is discretized on the simple rectangular structure in the new body fitted coordinate system. The influence of geometrical variations on relevant transport properties is studied. It is shown that the influence of the element size as well as of the order of the discretization scheme on the achieved accuracy and on the required computing time is in agreement with the results. This influence is not affected by the coordinate transformation. The concept of body fitted coordinate systems is applied to model the heat transport in a realistic complex structure. The effective conductivity of a perforated brass plate is modeled by averaging detailed information about the heat flux and about the temperature distribution. The averaging procedure is generalized to determine the possible anisotropic behavior due to the geometric complexity. ESA

A NUMERICAL INVESTIGATION OF THE ARTIFICIAL COMPRESSIBILITY METHOD FOR THE SOLUTION OF THE NAVIER-STOKES EQUATIONS
D. T. Elsworth and E. F. Toro Nov. 1992 17 p
(Cranfield-Aero-9213; ISBN-1-87-156455-7; ETN-94-95220) Avail: CASI HC A03/MF A01

Aspects of the numerical solution of the incompressible Navier-Stokes equations are examined. The artificial compressibility approach is a numerical method for solving the incompressible Navier-Stokes equations. The use of five different Riemann solvers for the equations of the artificial compressibility method is addressed. The performance of the Riemann solvers is examined. Four of these are approximate Riemann solvers and one is an exact solver. Three ways in which the boundary conditions can be treated are studied. The choice of c, the artificial compressibility coefficient, is investigated. ESA

(AD-A273740; WL-TR-93-2053) Avail: CASI HC A03/MF A01

The analysis of two-point velocity correlation measurement, made in the anisotropic flowfield of axisymmetric sudden expansion using two-single component LDV systems, has been performed. Estimations of the Taylor microscale were made and the one dimensional energy spectrum was determined using the spatial and autocorrelation functions from these measurements. Difficulties in estimating the Taylor microscale from spatial and autocorrelations are discussed and methods to overcome these difficulties are suggested. Calculations of the one dimensional energy spectrum from curve fits to the correlation functions are explored and some hazards of the process are highlighted. DTIC

OFF-DESIGN PERFORMANCE OF CRENULATED BLADES IN A LINEAR COMPRESSOR CASCADE M.S. Thesis
Michael J. Costello 1 Dec. 1993 133 p
(AD-A273744; AFIT/GAE/ENY/93D-9) Avail: CASI HC A07/MF A02

The effects of using compressor blades with a crenulated (notched) trailing edge in a low aspect ratio (AR = 1) linear compressor cascade at four incidence angles (-1.08 deg, +4.49 deg, +9.32 deg and +12.44 deg) were investigated. Blade performance and wake mixing characteristics for crenulated blades were compared with similar data for blades with a straight trailing edge. A seven-bladed cascade was operated with a flow Mach number of 0.4 and a blade chord Reynolds number of 4.1 x 10(exp

5). The diffusion factor ranged from 0.22 to 0.42 and strong three-dimensional flow effects were present. Total pressure losses were measured with a total pressure rake. Velocities and flow angles were measured using hot-film anemometry. Crenulated blades were found to enhance wake mixing from 20 to 50 percent depending on blade loading and downstream location. Crenulated blades were also found to reduce flow deflection by 1.9 deg at the lowest incidence and by 3.7 deg at the highest incidence. At the highest blade loading, crenulations were found to reduce total pressure losses by 20 percent and inhibit large scale flow degradation and vortex breakdown. At mild blade loadings, negligible differences in losses were observed. DTIC

PYROELECTRIC SENSORS IN COPOLYMER INTEGRATED ON SILICON Ph.D. Thesis - Toulouse Univ. [DETECTEURS PYROELECTRIQUES EN COPOLYMERE INTEGRES SUR SILICIUM]
Jean-Paul Beconne 1993 142 p In FRENCH
(LAAS-93044; ETN-94-95184) Avail: CASI HC A07/MF A02

The advantage of pyroelectric over semiconductor sensors for industrial applications is their low cost and their ability to work at room temperature. This advantage provided a context in which to study new materials such as polar polymers. Polyvinylidene fluoride and, one of its copolymers, polyvinylidene trifluro ethylene, were selected among polar polymers and applied to the problem of passive obstacle detection in a moving automobile. Copolymer sensors integrated on silicon are investigated. Successive processing steps are detailed: copolymer deposition in the liquid phase, characterization by electrooptical sensors, and modelization of the results from the characterization. The two deposition methods for the copolymer are compared, and the balance between their advantages and drawbacks is detailed. The main parameters involved in sensor technology are specified. ESA

Hydrogen leaks pose a constant fire and explosion threat, and existing techniques for detecting hydrogen suffer from a number of limitations. Existing hydrogen sensors have limited dynamic range, poor reproducibility and reversibility, are subject to false alarms, and tend to be slow, unreliable and difficult to use. In order to address this need, Sandia has designed, fabricated, tested, and demonstrated a new generation of hydrogen sensor which overcomes the limitations of existing technology. This new technology, known as the Robust, Wide-Range Hydrogen Sensor Technology, was created by integrating special catalytic alloy films into Sandia's existing CMOS micro-electronic based hydrogen sensor technology. The Sensor contains PdNi transistor sensors for detecting low concentrations of hydrogen, PdNi resistor sensors for detecting higher concentrations of hydrogen, and on-chip micro-thermometers and micro-heaters for maintaining constant chip temperature. (Contract DE-FG05-92ER-79119)
(DE94-001224; DOE/ER-79119/1) Avail: CASI HC A02/MF A01

A TG-151 Thermogravimetric Experimental Station, which measures and records weight changes of a solid material over a wide dynamic temperature range at a wide range of pressures in controlled environments, was purchased from Cahn Instruments, Inc. The TG-151 permits temperature to be programmed to follow a precise temperature profile of ramp and/or isothermal segments while monitoring the changes in weight of solid samples exposed to a gaseous environment of specified composition at a preset pressure. Weight and temperature measurements are made at user-specified time intervals and total time (up to 48 hours). Data are stored on the disk of a dedicated computer. The data can be processed by a data analysis program or exported to spreadsheet programs. The pressure vessel is designed to operate in vacuum to 10(exp -5) torr and over a wide range of pressures. At normal room temperature, the TG-151 can operate up to 100 atm and at 1273 K, it can operate up to 70 atm. The null balance has a sensitivity of 10 micrograms, capacity up to 100 grams, and a dynamic range of 10(exp 6):1. Both reducing and oxidizing environments can be established in the reaction chamber. For our specific needs the instrument had to be slightly modified to allow for two reactant gas streams to enter the pressure vessel at prescribed times. This required the purchase and installation of a gas blending system. The gas blending system permits coal and char samples to be heated at a specified rate to a desired temperature in an inert environment before the sample is exposed to an oxidizing environment. DOE

STEREO FOR GAZING AND CONVERGING CAMERAS. PART 1: BASIC GEOMETRY
David W. Murray 1992 15 p
(OUEL-1915/92; ETN-94-95144) Avail: CASI HC A03/MF A01

Geometrical descriptions of the imaging system of the common elevation configuration when fixating on an arbitrary point in space are developed, and the use of cyclotorsion to convert from one gazing system to another is indicated. The development of approximations for the disparity under small angle conditions is shown to be easier by referring points to the gazing cyclopean frame, rather than the primary or resting cyclopean frame, at least one piece of evidence in support of Ballard's assertion that this is the 'natural' reference frame. The approximations made are shown to be correct to first order even for points with large displacements from the optic axis in the cyclopean frame, and an approximation correct to second order when this displacement is small is obtained. GENERIC MICROELECTRONIC SMART SENSOR PLATFORM FOR DETECTION OF TOXIC, HAZARDOUS, AND FLAMMABLE GASES
J. Rodriguez, W. Corbett, S. Montague, M. Knoll, and P. McWhorter 1993 3 p Presented at the International Electron Devices Meeting, Washington, DC, 5-8 Dec. 1993
(Contract DE-AC04-76DP-00789)
(DE93-017626; SAND-93-1617C; CONF-931215-1) Avail: CASI HC A01/MF A01

Extensive work has been performed in the past which demonstrates that various metal alloys can be used to detect different toxic, hazardous, and flammable gases. Work has been performed using Pd, Pt, Ir, PdNi, PdAg and Pt/Pd for detecting things such as Hydrogen, Hydrazine, Hydrogen Sulfide, Deuterium, Tritium, Ethanol and Hexane. Perhaps the most familiar is the use of Pd and PdNi for the detection of Hydrogen. These devices work by examining the effect of the gases on the material properties of the metal alloys. Two of the most common material properties examined in these sensors are the resistance of thin film resistors, and the flatband or threshold voltage shifts of MOS structures fabricated with a particular alloy as the gate material. While research into these sensing techniques has shown much promise, few manufacturable, fieldable devices have resulted. These sensing techniques are prone to drift problems due to temperature variations, and typically have large sample to sample variations in performance due to process control issues. Typically, these sensors require significant external instrumentation for measurement and control, making the systems large and expensive. Sandia National Laboratories has designed, fabricated and demonstrated complete functionality of a generic microelectronic based smart sensor platform intended to effectively exploit the research mentioned above into high performance, manufacturable, fieldable devices. This smart sensor platform technology fabricates 2 (mu)m CMOS digital and analog control electronics, sensing elements, and temperature control elements on the same silicon integrated circuit. Our initial demonstration of this technology incorporates PdNi as the sensing alloy for the detection of hydrogen. DOE

DESIGN OF A SURFACE DEFORMATION MEASURING INSTRUMENT FOR THE SURFACE TENSION DRIVEN CONVECTION EXPERIMENT (STDCE-2) Final Technical Report
H. Philip Stahl 23 Dec. 1993 209 p
(Grant NAG3-1300)
(NASA-CR-194758; NAS 1.26:194758) Avail: CASI HC A10/MF A03

This final technical report covers the work accomplished (under NAG3-1300) from 1 October 1991 to 1 October 1993. The grant is a direct result of Dr. H. Philip Stahl's (of Rose-Hulman Institute of Technology) participation in the NASA/ASEE Summer Faculty Fellowship Program at NASA Lewis Research Center sponsored by Case Western Reserve University and the Ohio Aerospace Institute. The Surface Tension Driven Convection Experiment (STDCE) is a fundamental fluid physics experiment designed to provide quantitative data on the thermocapillary flow of fluid under the influence of an increased localized surface temperature. STDCE flew on the Space Shuttle Columbia in the First United States Microgravity Laboratory (USML-1) in June 1992. The second flight of this experiment (STDCE-2) is scheduled for 1995. The specific science objectives of STDCE-2 are to determine the extent and nature of thermocapillary flows, the effect of heating mode and level, the effect of the liquid free-surface shape, and the onset conditions for and nature of oscillatory flows. In order to satisfy one of these objectives, an instrument for measuring the shape of an air/oil free surface must be developed. Author (revised)

FEASIBILITY OF DETECTING AIRCRAFT WAKE VORTICES USING PASSIVE MICROWAVE RADIOMETERS Final Report
Richard F. Harrington Dec. 1993 47 p
(Contract NAS1-19858; RTOP 505-64-12-04)
(NASA-CR-191553; NAS 1.26:191553) Avail: CASI HC A03/MF A01

The feasibility of detecting the cold core of the wake vortex from the wingtips of an aircraft using a passive microwave radiometer was investigated. It was determined that there is a possibility that a cold core whose physical temperature drop is 10 C or greater and which has a diameter of 5 m or greater can be detected by a microwave radiometer. The radiometer would be a noise injection balanced Dicke radiometer operating at a center frequency of 60 GHz. It would require a noise figure of 5 dB, a predetection bandwidth of 6 GHz, and an integration time of 2 seconds resulting in a radiometric sensitivity of 0.018 K. However, three additional studies are required. The first would determine what are the fluctuations in the radiometric antenna temperature due to short-term fluctuations in atmospheric pressure, temperature, and relative humidity. Second, what is the effect of the pressure and temperature drop within the cold core of the wake vortex on its opacity. The third area concerns the possibility of developing a 60 GHz radiometer with a radio metric sensitivity an order of magnitude improvement over the existing state of the art. Author (revised)

HIGH TEMPERATURE, OXIDATION RESISTANT NOBLE METAL-Al ALLOY THERMOCOUPLE Patent
James L. Smialek, inventor (to NASA) and Michael G. Gedwill, inventor (to NASA) 4 Jan. 1994 7 p Filed 6 Jul. 1993 Supersedes N93-31298 (31 - 12, p 3729)
(NASA-Case-LEW-15515-1; US-Patent-5,275,670;
US-Patent-Appl-SN-086584; US-Patent-Class-136-236.1;
US-Patent-Class-136-241; Int-Patent-Class-H01L-35/12) Avail: US Patent and Trademark Office

A thermocouple is disclosed. The thermocouple is comprised of an electropositive leg formed of a noble metal-Al alloy and an electronegative leg electrically joined to form a thermocouple junction. The thermocouple provides for accurate and reproducible measurement of high temperatures (600 - 1300 C) in inert, oxidizing or reducing environments, gases, or vacuum. Furthermore, the thermocouple circumvents the need for expensive, strategic precious metals such as rhodium as a constituent component. Selective oxidation of rhodium is also thereby precluded.

REAL-TIME HOLOGRAPHIC ENDOSCOPY
P. Smigielski, F. Albe, and B. Dischli 27 Jan. 1992 11 p Presented at the SPIE Biomedical Optic 1992 International Symposium, Los Angeles, CA, 19-24 Jan. 1992
(ISL-CO-203/92; ETN-94-95122) Avail: CASI HC A03/MF A01

Experiments concerning holographic endoscopy are presented. The quantitative measurements of deformations of objects are obtained by the double exposure and double reference beam method using either a continuous wave laser or a pulsed laser. Qualitative experiments using an argon laser with time average holographic endoscopy are also presented. A video film on real time endoscopic holographic interferometry was recorded with the help of a frequency doubled YAG laser working at 25 Hz for the first time. ESA

MINIATURE CONVECTION COOLED PLUG-TYPE HEAT FLUX GAUGES
Curt H. Liebert Feb. 1994 16 p Proposed for presentation at the 40th International Instrumentation Symposium, Baltimore, MD, 1-5 May 1994; sponsored by the Instrument Society of America
(RTOP 505-62-50)
(NASA-TM-106483; E-8420; NAS 1.15:106483) Avail: CASI HC A03/MF A01

Tests and analysis of a new miniature plug-type heat flux gauge configuration are described. This gauge can simultaneously measure heat flux on two opposed active surfaces when heat flux levels are equal to or greater than about 0.2 MW/m(sup 2). The performance of this dual active surface gauge was investigated over a wide transient and steady heat flux and temperature range. The tests were performed by radiatively heating the front surface with an argon arc lamp while the back surface was convection cooled with air. Accuracy is about +20 percent. The gauge is responsive to fast heat flux transients and is designed to withstand the high temperature (1300 K), high pressure (15 MPa), erosive and corrosive environments in modern engines. This gauge can be used to measure heat flux on the surfaces of internally cooled apparatus such as turbine blades and combustors used in jet propulsion systems and on the surfaces of hypersonic vehicles. Heat flux measurement accuracy is not compromised when design considerations call for various size gauges to be fabricated into alloys of various shapes and properties. Significant gauge temperature reductions (120 K), which can lead to potential gauge durability improvement, were obtained when the gauges were air-cooled by forced convection. Author (revised)

INTEGRATED ACCELEROMETER ASSEMBLY Patent
Henry C. Abbink, inventor (to Litton Systems, Inc.) and Nicholas F. Pier, inventor (to Litton Systems, Inc.) 14 Sep. 1993 22 p
(CA-Patent-1322107; Int-Patent-Class-G01P-015/02; Int-Patent-Class-G01P-015/08; CTN-94-60935) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An integrated assembly is provided for a dry accelerometer of the pendulous mass type. The assembly includes a planar support base having an aperture in the center and a pendulous member including two arms. A pair of spaced flexible hinges having a first end of each attached to the support base and a second end of each attached to one of the arms pivotally support the pendulous member within the aperture. A pair of limit stops welded to opposed sides of the support base limit the movement of the pendulous member. The support base includes a plurality of apertures for anchoring the hinge welds and limit stop welds and the pendulous member includes a plurality of copper filled apertures for anchoring the hinge welds. Procedures for fabrication of the integrated assembly are also disclosed. The invention provides a means for relatively inexpensive and easy fabrication of dry accelerometer assemblies having less loss of accuracy over time compared to assemblies of the prior art. DOPPLER GLOBAL VELOCIMETRY: DEVELOPMENT OF A FLIGHT RESEARCH INSTRUMENTATION SYSTEM FOR APPLICATION TO NON-INTRUSIVE MEASUREMENTS OF THE FLOW FIELD Final Report
Hiroshi Komine, Stephen J. Brosnan, William H. Long, and Eddy A. Stappaerts 26 Jan. 1994 54 p Original contains color illustrations
(Contract NAS1-19440; RTOP 505-59-10-09)
(NASA-CR-191490; NAS 1.26:191490) Avail: CASI HC A04/MF A01; 4 functional color pages

Doppler Global Velocimetry (DGV) is a new diagnostic tool that offers potential for flow field measurements in flight by acquiring three-component velocity data in near real-time during flight maneuvers. The feasibility of implementation of a flight DGV system aboard NASA's High-Angle-of-Attack Research Vehicle (HARV) was addressed in this work by identifying the essential characteristics of a flight measurement system and by performing calibration and error tests. Results from this work were: an outline that establishes a preliminary basis for system configurations by analyzing measurement errors, installation issues, and operating requirements; measurement of the accuracy of the DGV technique using a laboratory breadboard DGV system based on a frequency-doubled Nd: YAG laser and iodine Absorption Line Filter (ALF), which showed excellent agreement between the DGV data and pilot measurements on a laminar flow jet with velocities of up to 150 m/sec; a survey of DGV system components and technologies that are relevant to the design of a flight measurement system, including a survey of cameras for the next generation DGV receivers; an assessment of the candidate lasers and absorption line filters for the flight system, resulting in a near-term recommendation of Nd: host lasers and an iodine ALF for both flight and wind tunnel applications. IMPROVED PRESSURE MEASUREMENT SYSTEM FOR CALIBRATION OF THE NASA LeRC 10X10 SUPERSONIC WIND TUNNEL
Philip Z. Blumenthal (Sverdrup Technology, Inc., Brook Park, OH.) and Stephen M. Helland Jan. 1994 16 p Proposed for presentation at the 40th International Instrumentation Symposium, Baltimore, MD, 1-5 May 1994; sponsored by the Instrument Society of America
(Contract NAS3-25266; RTOP 505-62-84)
(NASA-TM-106470; E-8338; NAS 1.15:106470) Avail: CASI HC A03/MF A01

This paper discusses a method used to provide a significant improvement in the accuracy of the Electronically Scanned Pressure (ESP) Measurement System by means of a fully automatic floating pressure generating system for the ESP calibration and reference pressures. This system was used to obtain test section Mach number and flow angularity measurements over the full envelope of test conditions for the 10 x 10 Supersonic Wind Tunnel. The uncertainty analysis and actual test data demonstrated that, for most test conditions, this method could reduce errors to about one-third to one-half that obtained with the standard system. METHOD AND APPARATUS FOR THE NON-INVASIVE MEASUREMENT OF PRESSURE INSIDE PIPES USING A FIBER OPTIC INTERFEROMETER SENSOR Patent
Gerard P. Carroll, inventor (to Navy) 8 Jun. 1993 6 p Filed 20 May 1991
(AD-D016013; US-Patent-5,218,197; US-Patent-Appl-SN-702540; US-Patent-Class-250-227.19) Avail: US Patent and Trademark Office

A method and apparatus for the non-invasive sensing of the pressure within a pipe (or other vessel) is disclosed. An optical source produces a first light beam. This first light beam is split between a first (reference) and a second (measurement) optical fiber. The second optical fiber is associated with the pipe such that circumferential displacements in the pipe, due to changes in internal pressure, result in corresponding displacements in the length of the second optical fiber. Length changes in the optical fibers result in variations in the phase of the light emerging therefrom. The phase difference between the light beams emitted from the first and second optical fibers is then determined and related to changes in the internal pressure of the pipe. DTIC

MEASUREMENT OF INTERFACIAL TENSION BY USE OF PENDANT DROP VIDEO TECHNIQUES

Melvin D. Herd, Charles P. Thomas, Gregory A. Bala, and Gordon D. Lassahn Sep. 1993 68 p
(Contract DE-AC07-76ID-01570)
(DE93-000168; DOE/ID-01570/T170) Avail: CASI HC A04/MF A01

This report describes an instrument to measure the interfacial tension (IFT) of aqueous surfactant solutions and crude oil. The method involves injection of a drop of fluid (such as crude oil) into a second immiscible phase to determine the IFT between the two phases. The instrument is composed of an AT-class computer, optical cell, illumination, video camera and lens, video frame digitizer board, monitor, and software. The camera displays an image of the pendant drop on the monitor, which is then processed by the frame digitizer board and non-proprietary software to determine the IFT. Several binary and ternary phase systems were taken from the literature and used to measure the precision and accuracy of the instrument in determining IFT's. A copy of the software program is included in the report. A copy of the program on diskette can be obtained from the Energy Science and Technology Software Center, P.O. Box 1020, Oak Ridge, TN 37831-1020. The accuracy and precision of the technique and apparatus presented is very good for measurement of IFT's in the range from 72 to 10(exp -2) mN/m, which is adequate for many EOR applications. With modifications to the equipment and the numerical techniques, measurements of ultralow IFT's (less than 10(exp -3) mN/m) should be possible as well as measurements at reservoir temperature and pressure conditions. The instrument has been used at the Idaho National Engineering Laboratory to support the research program on microbial enhanced oil recovery. Measurements of IFT's for several bacterial supernatants and unfractionated acid precipitates of microbial cultures containing biosurfactants against medium to heavy crude oils are reported. These experiments demonstrate that the use of automated video imaging of pendant drops is a simple and fast method to reliably determine interfacial tension between two immiscible liquid phases, or between a gas and a liquid phase. POLARIZATION ANALYSIS OF A BALLOON-BORNE SOLAR MAGNETOGRAPH Final Report

Daniel J. Reiley and Russell A. Chipman 14 Dec. 1993 58 p
(Contract NAS8-38609)
(NASA-CR-193908; NAS 1.26:193908) Avail: CASI HC A04/MF A01

The 10(exp -5) polarization specification for the Balloon-borne Vector Magnetograph (BVM) can be met. The 10(exp -5) specification is shown to be a limitation on the diattenuation and retardance along the chief ray path through the optical system, such that the magnitude of the polarization aberration piston term is constrained to be less than .5(10)(exp -5). Coating specification sheets are provided which will ensure that the polarization sensitivity of the BVM will be less than 10(exp -5). An optical design is provided for a vector magnetograph. Finally, to provide a concrete mathematical meaning for polarization sensitivity, the polarization aberration matrix is averaged of the exit pupil. This shows that the coupling between circular and linear states depends only on the magnitude of the polarization aberration piston term. Author (revised)

PERFORMANCE OF INVERSE PHOTOEMISSION SPECTROMETER WITH A NEW BANDPASS PHOTON DETECTOR OF NARROW BANDWIDTH AND HIGH SENSITIVITY

Yoshifumi Ueda, Katsuhiro Nishihara, Kojiro Mimura, Yasuko Hari, Masaki Taniguchi, and Masami Fujisawa Mar. 1993 18 p Sponsored by Ministry of Education, Science and Culture, Tokyo, Japan and Ogasawara Science and Technology Foundation, Japan
(Rept-A-2659; JTN-94-80530) Avail: CASI HC A03/MF A01

A combination of a SrF2 entrance window and a photomultiplier with the Cu-BeO first dynode coated with KCl film realizes the bandpass photon detector with the FWHM (Full Width at Half Maximum) of 0.47 eV centered at .43 eV and the sensitivity improved by about one order of magnitude in comparison with the detector without the KCl film. The overall energy resolution of the inverse photoemission spectrometer, consisting of an electron gun with a BeO cathode and the new detector, has been estimated to be 0.56 eV using polycrystalline Au. Typical counting rate is 10(exp 2) -10(exp 3) counts /(mu A sec) for unoccupied states near the Fermi level of the Au at an acceptance angle of about 0.8 pi steradians with an Al collecting mirror. ANALYSIS OF SOFCAL CALIBRATION DATA Final Report

John C. Gregory Dec. 1993 20 p
(Contract NAS8-38609)
(NASA-CR-193910; NAS 1.26:193910) Avail: CASI HC A03/MF A01

Ionization calorimeters determine the total energy of a particle by absorbing, within the mass of the calorimeter, the entire energy of the particle or a significant (and determinable) fraction of it. The JACEE group has used passive ionization calorimetery, which employs photographic emulsions as the detector medium, to measure the charge composition and energy spectrum of cosmic rays up to, and exceeding, 10(exp 14)eV. The SOFIC approach depends similarly on the use of three-dimensional nuclear-electromagnetic shower theory to relate the ionization deposits obtained during a shower to the energy of the particle causing the shower. Bundles of thousands of scintillating optical fibers are read out using image-intensified CCD's. Such an event may be triggered by a fast shower detector placed under the instrument or if only heavy particles are of interest, from a fast primary Cerention detector placed above the calorimeter. In the first study, fast Hammatsu photomultiplier tubes were purchased and tested for possible application for a triggering purpose. In the second study, some refinements have been made to the theoretical treatment of hadronic interactions in the central collision region. These will be helpful in improving the simulations necessary for observations of high energy cosmic ray nuclei with a SOFIC. Author (revised)

SYSTEM FOR CANCELLING PHASE NOISE IN AN INTERFEROMETRIC FIBER OPTIC SENSOR ARRANGEMENT Patent

Alan D. Kersey, inventor (to Navy) 13 Jul. 1993 11 p Filed 24 Apr. 1991
(AD-D015994; US-Patent-5,227,857; US-Patent-Appl-SN-690437; US-Patent-Class-356-345) Avail: US Patent and Trademark Office

A fiber optic sensor system for cancelling phase noise while it senses a measurand field is disclosed. The system includes circuitry for developing a light beam that is frequency modulated at a fundamental frequency. First and second unbalanced interferometers, having equal path imbalances, are responsive to the frequency modulated light beam for producing respective first and second optical outputs. Detection circuitry is responsive to the fundamental frequency, the second harmonic of the fundamental frequency, and the first and second optical outputs for producing a plurality of sine and cosine signals containing phase difference and phase noise components. A signal processor is responsive to the plurality of sine and cosine signals for cancelling the phase noise components and only producing output sine and cosine components of the difference in the phase shift between the first and second unbalanced interferometers. The system can further include a demodulator for demodulating the sine and cosine components to produce an output signal proportional to the phase shift difference between the first and second unbalanced interferometers. VLSI-BASED VIDEO EVENT TRIGGERING FOR IMAGE DATA COMPRESSION

Glenn L. Williams Feb. 1994 11 p Proposed for presentation at the 40th ISA International Instrumentation Symposium, Baltimore, MD, 1-5 May 1994; sponsored by the Instrument Society of America
(RTOP 694-03-OC)
(NASA-TM-106500; E-8512; NAS 1.15:106500) Avail: CASI HC A03/MF A01

Long-duration, on-orbit microgravity experiments require a combination of high resolution and high frame rate video data acquisition. The digitized high-rate video stream presents a difficult data storage problem. Data produced at rates of several hundred million bytes per second may require a total mission video data storage requirement exceeding one terabyte. A NASA-designed, VLSI-based, highly parallel digital state machine generates a digital trigger signal at the onset of a video event. High capacity random access memory storage coupled with newly available fuzzy logic devices permits the monitoring of a video image stream for long term (DC-like) or short term (AC-like) changes caused by spatial translation, dilation, appearance, disappearance, or color change in a video object. Pre-trigger and post-trigger storage techniques are then adaptable to archiving only the significant video images. Author (revised)

(AD-A273178) Avail: CASI HC A03/MF A01

Nanometer-scale manipulation of surfaces is important because subtle changes in surface structure often result in new electronic, magnetic, photonic, and mechanical materials properties. In this brief article we address one aspect of nanometer-scale surface manipulation that is of both technological and fundamental interest: scanning probe microscope (SPM)-induced patterning of surfaces. We begin by discussing traditional methods for submicron patterning, then we address some general aspects of SPM surface manipulation, and finally we present some specific results from our own laboratory. HIGH PRECISION X RAY LITHOGRAPHIC MASKS Final Report
R. F. Pease and R. Browning 1992 79 p
(Contract N00014-90-K-2000)
(AD-A273342) Avail: CASI HC A05/MF A01

This contract period was first concerned with winding up the projects on the embedded X-ray Mask structure and on the 'quantum lithography' idea. As a result of developments elsewhere it became clear that among the most critical issues in achieving high precision X-ray masks were those associated with achieving high precision in both feature size and feature placement in electron beam lithography. Most of the effort in this reporting period was aimed at achieving precision in feature size; notably an attack on the problem of proximity effects. There were two approaches: (1) A short term approach aimed at correcting effects in existing electron beam pattern generators (notably the ETEC MEBES 3 and 4) for feature sizes down 500 nm; and (2) A long term approach aimed at avoiding proximity effects by employing low energy electron exposure for feature size below 500 nm. THERMODYNAMIC MODELS FOR BOUNDING PRESSURANT MASS REQUIREMENTS OF CRYOGENIC TANKS
Neil T. VanDresar and Mark S. Haberbusch (Ohio Aerospace Inst., Brook Park.) Jan. 1994 11 p Presented at the 1993 Cryogenic Engineering Conference, Albuquerque, NM, 12-16 Jul. 1993; sponsored by Los Alamos National Laboratory
(RTOP 506-42-73)
(NASA-TM-106476; E-8403; NAS 1.15:106476) Avail: CASI HC A03/MF A01

Thermodynamic models have been formulated to predict lower and upper bounds for the mass of pressurant gas required to pressurize a cryogenic tank and then expel liquid from the tank. Limiting conditions are based on either thermal equilibrium or zero energy exchange between the pressurant gas and initial tank contents. The models are independent of gravity level and allow specification of autogenous or non-condensible pressurants. Partial liquid fill levels may be specified for initial and final conditions. Model predictions are shown to successfully bound results from limited normal-gravity tests with condensable and non-condensable pressurant gases. Representative maximum collapse factor maps are presented for liquid hydrogen to show the effects of initial and final fill level on the range of pressurant gas requirements. Maximum collapse factors occur for partial expulsions with large final liquid fill fractions. Author

An element of an extensive silicon pixel detector, developed for a suprathermal time of flight sensor and implemented in the satellite experiment Soho (Solar and Heliospheric Observatory) for energy estimation of low and high energy particles, is examined. Two dimensional computerized simulations were carried out in order to solve Poisson, transport, and continuity equations, so that electrical properties were obtained and functioning parameters were optimized. Energy resolution of the detector at room temperature was obtained with measurements with alpha particles and is shown to be limited by detector window thickness. The functioning principle of the asynchronously triggered readout electronics was established with measurements in the particle beam of an accelerator. The dependence of the measured detector signal on particle energy and species was estimated; the results were successfully compared to Monte Carlo calculations. The identification of molecule ions after passing through thin carbon foils is shown to be possible due to the pixel structure. ESA

ACTIVE CAMERA CALIBRATION FOR A HEAD-EYE PLATFORM USING A VARIABLE STATE DIMENSION FILTER
Philip F. McLauchlan and David W. Murray 1993 29 p Sponsored in part by EEC
(Grant SERC-GR/G-30003)
(OUEL-1975/93; ETN-94-95159) Avail: CASI HC A03/MF A01

A technique for calibrating a camera mounted on a controllable head/eye platform is presented. It uses the trajectories of an arbitrary number of tracked corner features to improve the calibration parameter estimates over time, utilizing a novel variable state dimension form of the Kalman filter. No special visual stimuli are required and no assumptions are made about the structure of the scene, other than that it is stationary relative to the head. The algorithm runs at 4 frames per second on a single transputer, and is fully integrated into an active vision system for object detection and tracking. Updated calibration parameters are regularly passed to the vision modules that require them. Although the algorithm requires an initial estimate of camera focal length, results are presented from real experiments demonstrating that convergence is achieved for initial errors up to fifty percent. One method of improving the transverse spatial coherence of x-ray lasers (XRL's) is by adaptive spatial filtering of XRL apertures using geometric shaping in the form of bowtie or wedge XRLS. However, we must maintain the desired geometric shapes in exploding foil or slab configurations during the lasing period. As a first step toward understanding lasing in such geometries, the behavior of simple stripe XRL's was studied. Past experience with stripe XRL's deposited on thick plastic substrates resulted in significantly weaker laser intensities as compared to line-focused slab XRL's. Possible reasons for this intensity reduction of stripe XRL's could include mixing at the laser boundary, and changes in plasma, kinetics, and hydrodynamic properties which affect laser gains and propagation. Experimental and theoretical characterizations of germanium line-focused and stripe XRL's are presented. Key experimental parameters we will study include images of emission profiles of the laser blow-off, angular divergences, XRL output intensities, and ionization balances as we vary XRL designs. The experimental results are compared with two-dimensional (2-D) laser deposition and hydrodynamics simulations using LASNEX, and the changes in ionization balances and level populations from post-processing LASNEX results are studied. LASER LINEWIDTH MEASUREMENT IN THE PRESENCE OF RIN AND USING THE RECIRCULATING SELF HETERODYNE METHOD
M. Groten and W. vanEtten Jul. 1992 27 p
(EUT-92-E-262; ISBN-9-06-144262-1; ETN-94-94769) Avail: CASI HC A03/MF A01

Laser linewidth measurements using the recirculating self heterodyne method are analyzed. Both the relative intensity noise (RIN) and the phase noise are considered. The delay time of the optical feedback loop is assumed to be considerably larger than the laser's coherence time, a condition to be met for unperturbed reconstruction of the laser spectrum. The superposition of the laser's phase noise spectrum on its RIN spectrum is shown. ESA

PROPERTIES OF THE TRANSFER MATRICES OF DEFLECTING MAGNET SYSTEMS FOR FREE ELECTRON LASER
Masaru Takao Jan. 1993 17 p In JAPANESE
(DE93-508257; JAERI-M-92-211) Avail: CASI HC A03/MF A01

The oscillation of the free electron laser (FEL) requires the high current and low emittance electron beam. The beam transport system should be achromatic and isochronous to preserve the brightness and the emittance of the electron beam. In this paper we clarify the algebraic properties of the transfer matrices of the magnetic deflection system, which is a key component in the beam transport line. DOE

A NEW AUTOMATIC DESIGN METHOD TO DEVELOP MULTILAYER THIN FILM DEVICES FOR HIGH POWER LASER APPLICATIONS
N. K. Sahoo and K. V. S. R. Apparao 1992 60 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-632490; BARC-1992/E/047) Avail: CASI HC A04 (US Sales Only)

Optical thin film devices play a major role in many areas of frontier technology like development of various laser systems to the designing of complex and precision optical systems. Design and development of these devices are really challenging when they are meant for high power laser applications. In these cases besides desired optical characteristics, the devices are expected to satisfy a whole range of different needs like high damage threshold, durability etc. In the present work a completely automatic design method based on Modified Complex Method was developed for designing of high power thin film devices. Unlike most of the other methods it does not need any suitable starting design. A quarterwave design is sufficient to start with. If required, it is capable of generating its own starting design. The computer code of the method is very simple to implement. This automatic design method is discussed and various practicable output designs generated by it are presented. The relative efficiency of the method along with other powerful methods was presented while designing a broadband IR antireflection coating. The method is also incorporated with 2D and 3D electric field analysis programs to produce high damage threshold designs. Some experimental devices developed using such designs are also presented. EVALUATION OF URANIUM TRANSITIONS FOR ISOTOPICALLY-SELECTIVE LASER INDUCED FLUORESCENCE WITH DIODE LASERS (TECHNICAL REPORT FOR ST064)
B. D. Cannon Oct. 1993 40 p
(Contract DE-AC06-76RL-01830)
(DE94-002000; PNL-8864) Avail: CASI HC A03/MF A01

Isotopically-selective excitation of uranium atoms by diode lasers can be the basis for a portable instrument to perform uranium isotopic assays in the field. Such an instrument would improve the ability of on-site inspections to detect and deter nuclear proliferation. Published and unpublished spectroscopic data on atomic uranium were examined to identify candidate transitions for isotopically-selective laser excitation with diode lasers. Eleven candidate transitions were identified and evaluated for their potential usefulness for a portable uranium assay instrument. Eight of these transitions are suitable for laser induced fluorescence using different excitation and detection wavelengths, which will improve sensitivity and elemental selectivity. Data sheets on the 25 uranium transitions in the wavelength range 629 nm to 1,000 nm that originate in the ground or first excited states of neutral atomic uranium are included. Each data sheet provides the wavelength, upper and lower energy levels, angular momentum quantum numbers, U-235 isotope shift (relative to U-238, and high-resolution spectra of weapons-grade uranium (93% U-235 and 7% U-238). Highly homogeneous and stable industrial materials which do not occur naturally are produced commercially by use of artificially synthesized starting materials, inorganic nonmetallic solids with ionic and covalent bonding. These technical ceramic materials are produced by sintering a powder, often at high-temperature and high-pressure. In the past 10 years, interest in high temperature structural ceramics has led to a search for starting materials with ideal properties for the production of high quality ceramic components. One of the most promising structural materials is silicon nitride. Powder control is very important in controlling the quality of the ceramics. The scope of the work is to reach a more fundamental insight into the processes taking place in the reactor. The knowledge should be used to optimize the process. Since the reactor is essentially an aerosol reactor, the different stages in particle formation are first investigated theoretically. NTIS

InGaAsP/InP BASED 1.3/1.55 MICRON VERTICAL CAVITY SURFACE EMITTING LASERS FOR WAVELENGTH DIVISION MULTIPLEXED HIGH SPEED DISTRIBUTED COMPUTING, PHASE 1 Final Technical Report, 26 Feb. - 26 Sep. 1993

M. K. Kilcoyne and Jeff W. Scott 11 Oct. 1993 49 p
(Contract DASG60-93-C-0048)
(AD-A271081) Avail: CASI HC A03/MF A01

Wavelength division multiplexed communication systems are becoming increasingly attractive for maximizing the data capacity of long range fiber optic links. Currently, distributed feedback (DFB) semiconductor lasers must be used due to the system requirements of precise single frequency lasers. The high cost of DFB lasers and associated control circuitry has made these systems too expensive for wide acceptance. In this research, the possibility of using wavelength division multiplexed arrays of single 1.55 micron InGaAsP vertical cavity surface emitting lasers has been analyzed. The laser arrays have the potential to dramatically reduce the costs of sources compared with distributed feedback laser arrays. This research has focused on the technologies of wafer fusion, step etching and current constriction to develop designs that meet wavelength division multiplexed system requirements. Experiments and modeling has shown that 4x4 arrays of vertical cavity lasers spaced 2 nm apart in wavelength are a realistic goal. The sixteen lasers would each be capable of launching single mode powers above 1 mw into a fiber at drive currents below 8 mA. DTIC

MANUFACTURING AND CHARACTERIZATION OF GaAs/AlGaAs MULTIPLE QUANTUMWELL RIDGE WAVEGUIDE LASERS

J. S. Wellen, F. Karouta, M. E. C. Schemmann, E. Smalbrugge, and L. M. F. Kaufmann Nov. 1992 88 p
(EUT-92-E-265; ISBN-9-06-144265-6; ETN-94-94772) Avail: CASI HC A05/MF A01

The manufacturing process for GaAs/AlGaAs ridge waveguide lasers made with quantum well structures was investigated. Broad area and narrow ridge lasers were produced and characterized. Laser arrays and flared waveguide lasers were manufactured and their performance was measured. A good technique for the inspection of layer structures was found to be the oxidation of cleaved facets. The manufacturing process produces well functioning devices. However, improvements to the etching of small ridges is desirable for deeper structures and the metallization of the back contact needs to be improved for better bonding. Laser chips can in this way be mounted on heatsinks. Further problems arise mainly with the breaking procedure resulting in poor mirror quality of quite a number of lasers. With broad area lasers, the quantum well structures give good results. Measurements show low internal absorption and transparency current densities. Narrow ridge lasers perform very well with continuous operation. Threshold currents as low as 10.8 mA were measured. Laser arrays show promising results. Problems due to geometrical inaccuracy can probably be solved by using a special light field mask and better cleaving of the laser chips. Of the flared waveguide lasers, the tapered versions in particular seem to function well. With improvement of the cavity shape, better results could be obtained. ESA

HIGH-ORDER SUM AND DIFFERENCE-FREQUENCY GENERATION IN HELIUM

J. K. Crane and M. D. Perry 12 May 1993 17 p Presented at the NATO Workshop, Han-Sur-Lesse, Belgium, 8-14 Jan. 1993
(Contract W-7405-eng-48)
(DE94-001064; UCRL-JC-114025; CONF-9301119-3) Avail: CASI HC A03/MF A01

High-order harmonic generation provides a new method for generating coherent, XUV radiation. These harmonics are characterized by a rapid, perturbative drop at low orders, followed by a broad plateau extending to photon energies of 150 eV in the lighter, rare gas atoms. An experimentally observed limit coincides with the theoretical limit for harmonic generation in neutral atoms given by the expression E(sub c)(eV)=IP(0)+3U(sub p)(I), where E(sub c) is the energy cutoff of the harmonic plateau, IP(O) is the field-free ionization potential and U(sub p) is the electron quiver energy at the maximum intensity, I, seen by the atom. As part of an effort to develop this technique into a general purpose XUV source, extensive work to understand the phase-matching between the harmonic and driving fields, and the resulting effect on the conversion efficiency, angular distribution and spectral brightness has been undertaken at several. Though, certain aspects of the harmonically generated radiation such as the polarization, relative strength of a given harmonic, and the plateau extent, are defined by the single atom-field interaction. Specifically, the single-atom harmonic spectrum is determined primarily by the interaction of a driven, quasi-free electron with the atomic potential. Using two independent fields, one can affect the electron motion by controlling the relative strength, polarization, and phase of the fields and alter the harmonic spectrum. In this paper, we discuss initial, two-color experiments where we drive the atom with two fields of different frequencies: 1053 nm (1(omega)) and 526 nm (2(omega)). In addition to the higher, odd harmonics, we observe sets of three additional peaks that we attribute to sum and difference-frequency generation between the two fields. By controlling the relative polarization between the two fields we can control the relative strength of the harmonic and mixing components, as well as the polarization of the output XUV photon. DOE

POWER BEAMING TO SPACE USING A NUCLEAR REACTOR-PUMPED LASER

R. J. Lipinski, D. K. Monroe, and P. S. Pickard 1993 8 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract DE-AC04-76DP-00789)
(DE94-001208; SAND-93-2244C; CONF-940101-5) Avail: CASI HC A02/MF A01

The present political and environmental climate may slow the inevitable direct utilization of nuclear power in space. In the meantime, there is another approach for using nuclear energy for space power. That approach is to let nuclear energy generate a laser beam in a ground-based nuclear reactor-pumped laser (RPL), and then beam the optical energy into space. Potential space applications for a ground-based RPL include (1) illuminating geosynchronous communication satellites in the earth's shadow to extend their lives, (2) beaming power to orbital transfer vehicles, (3) providing power (from earth) to a lunar base during the long lunar night, and (4) removing space debris. FALCON is a high-power, steady-state, nuclear reactor-pumped laser (RPL) concept that is being developed by the Department of Energy with Sandia National Laboratories as the lead laboratory. The FALCON program has experimentally demonstrated reactor-pumped lasing in various mixtures of xenon, argon, neon, and helium at wavelengths of 0.585, 0.703, 0.725, 1.271, 1.733, 1.792, 2.032, 2.63, 2.65, and 3.37 microns with intrinsic efficiency as high as 2.5%. Frequency-doubling the 1.733-micron line would yield a good match for photovoltaic arrays at 0.867 microns. Preliminary designs of an RPL suitable for power beaming have been completed. The MW-class laser is fairly simple in construction, self-powered, closed-cycle (no exhaust gases), and modular. This paper describes the FALCON program accomplishments and power-beaming applications. DOE

VAPORIZATION BEHAVIOR OF NON-STOICHIOMETRIC REFRACTORY CARBIDE MATERIALS AND DIRECT OBSERVATIONS OF THE VAPOR PHASE USING LASER DIAGNOSTICS

D. P. Butt, P. J. Wantuck, S. J. Rehse, and T. C. Wallace, Sr. 1993 13 p Presented at the NATO Advanced Research Workshop on Corrosion of Advanced Ceramics, Tubingen, Germany, 30 Aug. - 3 Sep. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE93-040094; LA-UR-93-2942; CONF-9308163-1) Avail: CASI HC A03

Transition metal and actinide carbides, such as ZrC or NbC and UC or ThC, exhibit a wide range of stoichiometry, and therefore vaporize incongruently. At long times, steady state vaporization can be achieved where relative concentrations of atomic species on solid surface equals that in the gas phase. The surface composition under these steady state conditions is termed the congruently vaporizing composition, (CVC). Modeling the vaporization or corrosion behavior of this dynamic process is complex and requires an understanding of how the surface composition changes with time and a knowledge of CVC, which is both temperature and atmosphere dependent. This paper describes vaporization and corrosion behavior of non-stoichiometric refractory carbide materials and, as an example, describes a thermokinetic model that characterizes the vaporization behavior of the complex carbide U(x)Zr(1-x)C(y) in hydrogen at 2500 to 3200 K. This model demonstrates that steady state corrosion of U(x)Zr(1-x)C(y) is rate limited by gaseous transport of Zr where partial pressure of Zr is determined by CVC. This paper also briefly describes efforts to image and characterize the vapor phase above the surface of ZrC in static and flowing gas environments using planar laser induced fluorescence. We have developed the method for monitoring and controlling the corrosion behavior of nuclear fuels in nuclear thermal rockets. However, the techniques described can be used, to image boundary layers, and could be used verifying corrosion models. DOE

CHARACTERIZATION OF HEAT TRANSPORT AND RADIATION HYDRODYNAMICS IN COLLISIONAL LASER PLASMAS USING COLLECTIVE THOMSON SCATTERING
S. M. Cameron 1993 7 p Presented at the 6th International Symposium on Laser-Aided Plasma Diagnostics, Bar Harbor, ME, 25-28 Oct. 1993
(Contracts DE-AC04-94AL-85000; W-7405-eng-48)
(DE94-001502; SAND-93-2182C; CONF-9310195-1) Avail: CASI HC A02/MF A01

The author proposes using the collective Thomson scattering lineshape from ion acoustic waves to measure the spatial structure of local heat transport parameters and collisionality. Ion acoustic peak height asymmetry is used in conjunction with a recently developed model describing the effects of collisional and Landau damping contributions on the low-frequency electron density fluctuation spectrum to extract the relative electron drift. The local heat flux q(sub e) (proportional to drift) and the electron thermal conductivity (kappa)(sub e(approximately)) - q(sub e)/(gradient)T(sub e) would be inferred from experimentally determined temperature gradients (gradient)T(sub e). Damping of the entropy wave component at zero mode frequency is shown to be an estimate of the ion thermal conductivity (kappa)(sub i), and its visibility is a direct measure of the ion-ion mean free path (lambda)(sub ii). LASER LIGHT SCATTERING INSTRUMENT ADVANCED TECHNOLOGY DEVELOPMENT Final Report
J. F. Wallace Sep. 1993 10 p
(Contract NCC3-74)
(NASA-CR-194803; NAS 1.26:194803; CWRU-342-7658) Avail: CASI HC A02/MF A01

The objective of this advanced technology development (ATD) project has been to provide sturdy, miniaturized laser light scattering (LLS) instrumentation for use in microgravity experiments. To do this, we assessed user requirements, explored the capabilities of existing and prospective laser light scattering hardware, and both coordinated and participated in the hardware and software advances needed for a flight hardware instrument. We have successfully breadboarded and evaluated an engineering version of a single-angle glove-box instrument which uses solid state detectors and lasers, along with fiber optics, for beam delivery and detection. Additionally, we have provided the specifications and written verification procedures necessary for procuring a miniature multi-angle LLS instrument which will be used by the flight hardware project which resulted from this work and from this project's interaction with the laser light scattering community. A calculation on the stabilization of the sideband instability in the free electron laser (FEL) and inverse FEL (IFEL) was completed. The issue arises in connection with the use of a tapered ('variable-parameter') undulator of extended length, such as might be used in an 'enhanced efficiency' traveling-wave FEL or an IFEL accelerator. In addition, the FEL facility at Columbia was configured as a traveling wave amplifier for a 10-kW signal from a 24-GHz magnetron. The space charge field in the bunches of the FEL was measured. Completed work has been published. DOE

This is a summary of a research project that has come to be known as SUNLITE, initially standing for Stanford University - NASA laser in space technology experiment. It involves scientists from the NASA Langley Research Center (LaRC), Stanford University, the National Institute of Standards and Technology (NIST), and the Joint Institute for Laboratory Astrophysics (JILA), and a growing number of other institutions. The long range objective of the SUNLITE effort is to examine the fundamental linewidth and frequency stability limits of an actively stabilized laser oscillator in the microgravity and vibration-free environment of space. The ground-based SUNLITE activities supporting that objective will develop a space-qualified, self-contained and completely automated terahertz oscillator stabilized to a linewidth of less than 3 Hz, along with a measurement system capable of determining laser linewidth to one part in 10(exp 16). The purpose of this paper is to discuss the critical technologies needed to place stabilized lasers in space and to describe the progress made by the SUNLITE project to develop these technologies. EXCIPLEX LASER STUDY: DISCHARGE AND MAGNETIC SWITCHING SYSTEMS Final Report [ETUDE DES LASERS EXCIPLEXES: SYSTEMES A DOUBLE DECHARGE ET COMMUTATION MAGNETIQUE]
P. Delaporte Nov. 1992 42 p In FRENCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-199768) Avail: Issuing Activity (National Technical Information Service (NTIS))

The goal of the study was to make a repetitive excimer laser with a double discharge and magnetic switching circuit that is capable of firing impulses lasting 500 nanoseconds. The authors compared different types of electrical circuits based on double discharge and magnetic switching, as well as switch, diode, and overshoot modes to see which would produce the best results in repetitive mode. Their study showed that the laser performance of switch and overshoot modes are very close, but overshoot requires less magnetic material, which can lead to faster energy injection if the inductance of the laser head is low enough. The 3-5 based devices such as FET's, HBT's, and lasers often have surface leakage and thermal degradation problems due to surface states which pin the Fermi level to the mid-gap. Sulfur based passivation processes are known to improve device performance by altering surface-state densities. The authors have developed a voltage-controlled anodic sulfur passivation scheme using Na2S dissolved in ethylene glycol. Their process has repeatedly produced a approximately 25% improvement in peak output power near the catastrophic damage limit in visible (lambda = 670 nm) AlGaInP edge-emitting lasers. The threshold current density and electrical characteristics were unchanged after catastrophic failure indicating that passivation raises the threshold for facet damage. DOE

Currently, research is being conducted on the optical properties of materials associated with the development of solid state lasers in the two micron region. In support of this effort, a mathematical model describing the energy transfer in a holmium laser sensitized with thulium is developed. In this paper, we establish some qualitative properties of the solution of the model, such as non-negativity, boundedness, and integrability. A local stability analysis is then performed from which conditions for asymptotic stability are attained. Finally, we report on our numerical analysis of the system and how it compares with experimental results. Author (revised)

We have designed, built, tested, and operated a 70-period electromagnet planar microwiggler for use in free electron lasers (FEL's), constructed of current conductors wound on ferromagnetic cores. The device has an 8.8 mm period and a 4.2 mm gap and produces 0.5-msec magnetic field pulses of greater than 4.0 kG at a rate of 1/2 Hz. The field of each half-period of the wiggler is independently adjustable; we have developed a novel tuning regimen and employed it to reduce the RMS spread in peak amplitude of a uniform field profile to 0.12%, the best of any sub-cm period wiggler of which we are aware. In addition, the field at the ends of the wiggler have been tapered for reduced electron-beam steering and deflection. DTIC

NONLINEAR DYNAMICAL CONTROL OF LASERS Final Report
30 Oct. 1993 57 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-C-0053)
(AD-A273359) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Schwartz Electro-Optics, Inc. (SEO) was awarded this Small Business Innovation Research (SBIR) Phase I program entitled, Nonlinear Dynamical Control of Laser under Contract No. N0001 4-93-C-0053 from the Office of Naval Research (ONR), Arlington, VA. SEO successfully demonstrated stable blue-green output via second harmonic generation (SHG) from a solid state laser using a KNbO3 crystal in an external resonant cavity. The experiments were conducted at SEO, Orlando, Florida while the computer modelling was subcontracted to Dr. Donna Bandy's group at Oklahoma State University (OSU). The physics of lasers and SHG devices and their combination, naturally involves random chaotic fluctuations that can be attributed to the system nonlinearities. Controlling this behavior is demonstrated and a fundamental understanding of the role of the nonlinearities is exploited. DTIC

LASER-DEPOSITED BIOCOMPATIBLE FILMS AND METHODS AND APPARATUSES FOR PRODUCING SAME Patent
Catherine M. Cotell, inventor (to Navy), Douglas H. Chrisey, inventor (to Navy), Kenneth S. Grabowski, inventor (to Navy), and James A. Sprague, inventor (to Navy) 7 Sep. 1993 11 p Filed 31 Jul. 1991 Supersedes AD-D015181
(AD-D016017; US-Patent-5,242,706; US-Patent-Appl-SN-738362; US-Patent-Class-427-2) Avail: US Patent and Trademark Office

Biocompatible material can be deposited onto a substrate by laser deposition, such as pulsed laser beam deposition and ion-assisted pulsed laser beam deposition. The deposition can be done at room temperature, in a variety of different atmospheres, with control over the stoichiometry, adhesion, and porosity of the deposited film. The apparatus for carrying out the deposition, and articles formed by such deposition, are also described. The articles so formed are particularly useful as medical prosthesis such as implants. DTIC

TUNABLE LASERS PUMPED BY VISIBLE LASER DIODES Patent
Richard Scheps, inventor (to Navy) 28 Sep. 1993 12 p Filed 28 May 1992
(AD-D016000; US-Patent-5,249,189; US-Patent-Appl-SN-894508; US-Patent-Class-372-20) Avail: US Patent and Trademark Office

A laser having a Cr(3+) doped Colquiriite mineral host gain element, such as Cr:LiCAF, Cr:LiSAF or Cr:LiSGAF, is pumped by the pumping beam from at least one visible laser diode to provide tunable laser emission. The Cr(3+) doped Colquiriite mineral host gain element has an exterior face provided with a dichroic coating highly transmissive to the pumping beam and highly reflective to the tunable laser emission and has an interior face provided with an AR coating antireflective to the tunable laser emission. An output coupler mirror, provided with a coating that is partially reflective to the tunable laser emission, has an appropriate radius of curvature and is appropriately located to concentrate reflected tunable laser emission in a waist in a resonator mode on an exterior face of the Cr(3+) doped Colquiriite gain element to assure the visible light diode pumping thereof. A lens is disposed to receive the pumping beam to focus it at or near the waist on the exterior face of the Cr(3+) doped Colquiriite gain element. DTIC

INTERNALLY FOLDED SCALABLE LASER Patent
Richard Scheps, inventor (to Navy) 28 Sep. 1993 16 p Filed 21 May 1992
(AD-D015978; US-Patent-5,249,196; US-Patent-Appl-SN-887202; US-Patent-Class-372-93) Avail: US Patent and Trademark Office

An internally folded scalable laser is presented. The laser has a gain medium with an internal face and an external face and at least one internal fold face subtending an angle which may be about 90 deg. An output coupler that is partially reflective of the resonator mode is oriented to receive and reflect the resonator mode in a direction normal to the internal face to avoid resonator mode astigmatism and to define a folded hemispherically-shaped resonator cavity extending from the output coupler and through an active volume in the gain medium to the external face. A pumping mode source disposed adjacent to the external face is oriented to focus a first pumping mode in a direction normal to the external face in a boom waist at or inside the external face in the folded resonator cavity to define an active volume in the gain medium and to avoid pumping mode astigmatism. Other pumping mode sources direct more pumping mode through the internal-fold faces into a portion of the active volume to partially or completely overlap the pumping and resonator modes. Simultaneously pumping the gain medium along more than one axis for each fold surface assures scaling and physical separation of the pumped regions reduces thermal lensing problems. Other angles between the external and internal faces could be formed in multifaceted configurations of the gain medium so long as the pumping mode beam is normal to the external face and the resonator mode beam is normal to the internal face. THE EVOLUTION OF THE LASER: A SYSTEMS PERSPECTIVE ON SCIENCE, TECHNOLOGY AND SOCIETY Ph.D. Thesis [DE EVOLUTIE VAN DE LASER: EEN SYSTEEMPERSPECTIEF OP WETENSCHAP, TECHNOLOGIE EN SAMENLEVING]
Willem deRuiter 1992 362 p In DUTCH
(ETN-94-95319) Avail: CASI HC A16/MF A03

The evolution of laser technology is addressed, and an attempt is made to correlate this evolution to the macrosociological theory of Juergen Habermas. The economic and social consequences of innovations are evaluated. Different laser applications are described. The evolution of the semiconductor laser is discussed. The evolution of optical telecommunication systems is outlined. The Habermas theory of communicative action, focussing on the theoretical distinction between 'system' and 'lifeworld,' is treated. The modified theory of Habermas is applied to the evolution of the laser. The embedding of a number of laser applications in the social context is discussed: laser isotope separation, compact disc players, and the Strategic Defense Initiative. ESA

LASER ABLATION AND DEPOSITION OF METALS Ph.D. Thesis
Jacques Constant Ste Kools 1992 163 p Prepared in cooperation with Philips Gloeilampenfabrieken N.V., Eindhoven, Netherlands
(ETN-94-95311) Avail: CASI HC A08/MF A02

The processes and applications of laser ablation deposition (LAD), also known as pulsed laser deposition (PLD), which is the deposition of a physical thin film, are introduced. The main advantages of this technique, when compared to other thin film deposition techniques, are enumerated. The time of flight (TOF) system which is used to perform angular resolved TOF measurements on the deposition flux (atoms, ions, and molecules) generated by the ablation process, and which consequently provides means to characterize this flux, is described. A UHV deposition system for LAD of metals and nitrides is also discussed. The excimer lasers and UV optics used in LAD, and the methods of calibration of the fluence, are described. The following are also considered: kinetic energies of ablated neutrals, ionized species in the ablation plume, light emission by ablation plumes, deposition of metallic multilayers, and deposition of TiN films. MICROWAVE EXCITATION OF PULSED HIGH PRESSURE GAS DISCHARGE LASERS Ph.D. Thesis - Ruhr Univ. [MIKROWELLENANREGUNG VON GEPULSTEN HOCHDRUCK-GASENTLADUNGSLASERN]
Frank Gekat Feb. 1993 145 p In GERMAN
(Contract BMFT-13-N-55-45)
(DLR-FB-93-12; ETN-94-95201) Avail: CASI HC A07/MF A02

The microwave discharge as alternative means to the TEA and electron beam discharges is investigated. Experiments were performed with the XeCl excimer laser and the Xe laser. The theory of high pressure discharges was reviewed with special emphasis on microwave discharges. For experimental purposes a transversely propagative coupling structure was developed and numerically analyzed. The discharges were operated in two ways: directly with the discharge matched to the transmitter during the laser emission and indirectly by storing the microwave energy in a resonator comprising also the discharge vessel. By igniting the gas discharge the microwave resonator was discharged rapidly producing microwave pulses with power levels exceeding the transmitter power. This pulse compression technique facilitated the realization of a microwave excited XeCl laser with pulse energies exceeding 4 mJ. ESA

THE EFFECTS OF OPTICAL FEEDBACK ON POLARIZATION OF VERTICAL CAVITY SURFACE EMITTING LASERS M.S. Thesis
Gregory J. Vansuch Dec. 1993 61 p
(AD-A273728; AFIT/GAP/ENP/93D-09) Avail: CASI HC A04/MF A01

Vertical Cavity Surface Emitting Lasers (VCSEL's) are a type of semiconductor laser with a cavity oriented orthogonally to the planes of material growth. These lasers differ from conventional edge emitting lasers in several important ways. They have symmetric output beams and they are easily built into two dimensional arrays, making them very attractive as photonic components. The characteristic of interest is polarization. While the asymmetric cavities of edge emitters exhibit a clear preference for light polarized in a particular direction, the cylindrically symmetric cavity of a VCSEL has no clear preference. Therefore, it should be relatively easy to change the polarization of a VCSEL. The polarization switching effects of optical feedback from an external reflector are examined. By feeding back various amounts of cross-polarized light, the switching susceptibility of the VCSEL can be determined. Measurements confirmed that the polarization of a VCSEL can be switched through polarized optical feedback, with the degree of switching depending on the strength of feedback. This switching was a relatively rare behavior, indicating that most VCSEL's had some type of preferential polarization. This preference could be due to the VCSEL structure itself or the manner in which it was excited. DTIC

ECONOMICS OF ELECTRON BEAM AND ELECTRICAL DISCHARGE PROCESSING FOR POST-COMBUSTION NO(x) CONTROL IN INTERNAL COMBUSTION ENGINES
B. M. Penetrante 2 Aug. 1993 8 p Presented at the 6th Strategic Defense Initiative Organization/Office of Naval Research (SDIO/ONR) Pulse Power Meeting, Chicago, IL, 9-11 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-019574; UCRL-JC-114927; CONF-9308145-1) Avail: CASI HC A02

The physics and chemistry of non-thermal plasma processing for post-combustion NO(x) control in internal combustion engines are discussed. A comparison of electron beam and electrical discharge processing is made regarding their power consumption, radical production, NO(x) removal mechanisms, and by-product formation. Pollution control applications present a good opportunity for transferring pulsed power techniques to the commercial sector. However, unless advances are made to drastically reduce the price and power consumption of electron beam sources and pulsed power systems, these plasma techniques will not become commercially competitive with conventional thermal or surface-catalytic methods. METHOD FOR SIMULATING A VEHICLE SHOCK TEST: DESIGN AND REALIZATION OF THE REQUIRED IMPLEMENTATION TOOLS Ph.D. Thesis [METHODOLOGIE DE SIMULATION D'UN ESSAI DE CHOC DE VEHICULE: CONCEPTION ET REALISATION DES OUTILS NECESSAIRES A SA MISE EN OEUVRE]
Jean-Paul Mizzi 1992 498 p In FRENCH
(ECL-92-14; ETN-94-95167) Avail: CASI HC A21/MF A04

A mathematical multibody model which simulates the behavior of a passenger car during various frontal crash configurations is presented. A formulation of the motion equations based on the Lie group of displacements is considered. The main difficulty is to know the laws of behavior of the springs. An identification method from the configuration of the experimental results was envisaged. In order to know the vehicle real behavior during a crash trial, it is necessary to have experimental devices which make it possible to rebuild the space kinematics of the components. In each case, the acquisition and processing suitable software was designed. Different nonparametric and parametric identification methods were tested on simple and complex models. The results highlight the model most adapted to solve the problem. ESA

A system for coupling two bodies together and for transmitting torque from one body to another with mechanical timing and sequencing is reported. The mechanical timing and sequencing is handled so that the following criteria are met: (1) the bodies are handled in a safe manner and nothing floats loose in space, (2) electrical connectors are engaged as long as possible so that the internal processes can be monitored throughout by sensors, and (3) electrical and mechanical power and signals are coupled. The first body has a splined driver for providing the input torque. The second body has a threaded drive member capable of rotation and limited translation. The embedded drive member will mate with and fasten to the splined driver. The second body has an embedded bevel gear member capable of rotation and limited translation. This bevel gear member is coaxial with the threaded drive member. A compression spring provides a preload on the rotating threaded member, and a thrust bearing is used for limiting the translation of the bevel gear member so that when the bevel gear member reaches the upward limit of its translation the two bodies are fully coupled and the bevel gear member then rotates due to the input torque transmitted from the splined driver through the threaded drive member to the bevel gear member. An output bevel gear with an attached output drive shaft is embedded in the second body and meshes with the threaded rotating bevel gear member to transmit the input torque to the output drive shaft. A split spline screw type payload fastener assembly, including three identical male and female type split spline sections, is discussed. The male spline sections are formed on the head of a male type spline driver. Each of the split male type spline sections has an outwardly projecting

load baring segment including a convex upper surface which is adapted to engage a complementary concave surface of a female spline receptor in the form of a hollow bolt head. Additionally, the male spline section also includes a horizontal spline releasing segment and a spline tightening segment below each load bearing segment. The spline tightening segment consists of a vertical web of constant thickness. The web has at least one flat vertical wall surface which is designed to contact a generally flat vertically extending wall surface tab of the bolt head. Mutual interlocking and unlocking of the male and female splines results upon clockwise and counter clockwise turning of the driver element.

THE DESIGN OF A TURBINE VANE COOLING SYSTEM USED IN THE TOPPING CYCLE
P. T. Ireland and T. V. Jones Nov. 1992 43 p
(OUEL-1963/92; ETN-94-95150) Avail: CASI HC A03/MF A01

The design of a cooling system for a cascade of two dimensional blades tested in the side stream is described. The measured discharge through the three blade, accurately manufactured model agrees well with predictions from the design analytic model. A water flow rig was built and used to investigate the effect of reducing the trailing edge feed tube pressure on the flow distribution. Analysis of the coolant flow rates during the commissioning tests indicated that coolant was being lost from the leading edge tube delivery system. The measured coolant flow rate to the trailing edge tubes during commissioning was very close to the predicted value. The predicted blade temperatures are all within approximately 20% of the measured temperatures. The temperature differences are explainable in terms of uncertainty in the analytic model. ESA

TIME-FREQUENCY DOMAIN ANALYSIS OF VIBRATION SIGNALS FOR MACHINERY DIAGNOSTICS.(4): INTERPRETATION USING IMAGE PROCESSING TECHNIQUES
W. J. Wang and P. D. McFadden 1992 27 p Sponsored by United Kingdom Science and Engineering Research Council
(OUEL-1953/92; ETN-94-95148) Avail: CASI HC A03/MF A01

A system which uses image processing techniques to assist in the automatic interpretation of gear vibration signatures for early failure detection and fault diagnosis is described. The time signature of an individual gear in a gearbox is extracted by the time domain synchronous averaging technique from the total vibration signal measured in the gearbox casing. The time frequency distribution of the gear vibration signature, determined from the local power spectral density, is treated as an image, and the early failure detection and fault diagnosis are performed by interpreting the patterns in the image by the procedures of segmentation, connectivity analysis, and feature extraction. The implementation of the technique, the criteria for analysis of the image, and experimental examples are described. ESA

(DE94-001365; DOE/ID-13074/T9) Avail: CASI HC A03/MF A01

K-State has concluded the first quarter of the third year, demonstrating and evaluating electric vehicle technology. The G-Van has failed to operate during this period. Although plans are being made to install new batteries in the G-Van, the vehicle has little to prove or demonstrate in the way of advanced technologies. As such, there was an agreement by the Site Operator Users Task Force that no additional federal funding would be spent to maintain or operate the G-Vans. The DSEP van, received from DOE during the latter part of January remains idle. The DSEP vehicle may never be refurbished and used in the Site Operator Program as an operational vehicle. It may be used as a lab vehicle or in a special projects capacity. The cost of operating or maintaining this one-of-a-kind vehicle is high and the value of the vehicle to the program is questionable. Kansas State University is using and is pleased with its first Soleq's EVcort. The vehicle has been used on a routine basis around campus, at the Nebraska State Fair, the Kansas State Fair, and other specific functions. The vehicle continues to operate in an efficient manner, is well received by the public, and clearly demonstrates what is possible in EV technology. Professor Hague continued to serve as the Chairman of the Site Operator Users Task Force. As such, K-State is involved at all levels in promoting electric vehicle legislation and technology. The electric vehicle technology continues to be debated and discussed at all levels of government. The next year should bring incremental improvements for funding. The SOUTF has established an effort to 'push' the EV technology forward with the development of a common specification to be used in the purchase of electric vehicles during the next year. DOE

An improved engine suspension system is provided for attenuating vibration in a gas turbine engine. In one embodiment, the invention is directed to an aircraft engine suspension system for mounting a gas turbine engine to a supporting frame by mounts arranged in first and second parallel, spaced axial mounting planes of the engine. First and second vibration isolation mounts are aligned in the first mounting plane and couple the engine to the supporting frame. Each of the first and second mounts provides both radial and axial vibration damping to the engine as well as radial and axial stiffness. A third vibration isolation mount is aligned in the second mounting plane and couples the engine and support frame together to provide radial and tangential vibration damping to the engine as well as radial and tangential stiffness. The mounts are arranged axially and radially such that the suspension system is statically and dynamically determinate.

WELD CLADDING OF HARD SURFACES
T. Habrekke 1 Feb. 1993 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-201598; STF20-A93022) Avail: Issuing Activity (National Technical Information Service (NTIS))

A literature study about clad welding of hard surfaces on steel is performed. The purpose was to see what kind of methods are mainly used, and particular attention is paid to clad welding of rolls. The main impression from this study is that several methods are in use. Some of these must be considered as 'too exotic' for the aim of the program, such as laser build-up welding. However, clad welding of hard surfaces to rolls is widely used around the world, and there is no need for particularly advanced welding methods to perform the work. The welding consumables and the way the welding is carried out is of more important character. The report will give some comments to this, and hopefully will give a short review of the current technology in this field. NTIS

PLASMA ARC KEYHOLE WELDING OF ALUMINUM
H. Fostervoll 8 Feb. 1993 49 p Sponsored by Nordisk Industrifond Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-201606; STF20-A93032) Avail: Issuing Activity (National Technical Information Service (NTIS))

An increasing and more advanced use of aluminum as a construction material make higher demands to the effectiveness and quality in aluminum joining. Furthermore, if the advantages of aluminum shall be exploited in the best possible way, it is necessary to use the best processes available for the certain application. Today, the most widely used processes of aluminum welding are gas metal arc welding (GMAW) and gas tungsten arc welding (GTAW). Plasma arc welding (PAW) is another interesting process, which is rather newly adopted for aluminum welding. However, up to now the use is limited and most of the users are within the space industry in USA (NASA); also the new space industry in Europe has adopted the process. The reason for the great interest for PAW in the space industry is, according to NASA, higher weld quality and less repair costs, less heat distortion, and less groove preparations costs. Of these reasons, PAW should also be of interest for the aluminum industry in Scandinavia. The aim of the project is to focus on the possibilities and to some extent testing the PAW process. NTIS

NEW METHOD FOR INCREASING MACHINE SERVICE-LIFE, PHASE 2 Final Report
Alfred M. Ajami Oct. 1992 19 p Sponsored by NSF, Washington, DC
(Grant NSF MSM-85-00195)
(PB93-200707; NSF/ISI-92005) Avail: CASI HC A03/MF A01

The service life of lubricants used in high-speed small bearings can limit the use life of the mechanical system; such service life is dependent upon the oxidation resistance of the lubricant. Lubricant additives are used to protect the lubricant from oxidation and additive service life becomes the system limiting factor. A method of increasing the service life of lubricant additives is to alter their rate of chemical oxidation through deuteration at primary sites of reaction. Researchers previously demonstrated the feasibility of increasing the service life of a class of lubricant additives, the zinc dialkyldithiophosphates, by deuteration to prevent nucleophilic substitution at the alpha-carbon in the alkyl chain. In the Phase II program, attempts were made to scale up the synthesis procedures used to prepare four deuterated zinc dialkyldithiophosphates. The products, provided to a commercial formulator of bearing lubricants, were observed to increase the acidity of the additive and cause the lubricant to have a noxious odor. Considerable efforts to purify the additives did not solve the problems.

A cryocondensation pump, cooled by forced flow of two-phase helium, has been installed for particle exhaust from the divertor region of the DIII-D tokamak. The Inconel pumping surface is of coaxial geometry, 25.4 mm in outer diameter and 11.65 m in length. Because of the tokamak environment, the pump is designed to perform under relatively high pulsed heat loads (300 Wm(exp -2)). Results of measurements made on the pumping characteristics for D2, H2, and Ar are discussed. DOE

The present invention discloses bola bodies, bolas, and a snaring method which makes use such devices. A bola body, according to the present invention, is nonspherical or irregular in shape rather than a smooth sphere or ovoid body. One or more fingers extends from the bola body. These fingers may be relatively straight or they may have crooked or bent portions to enhance entanglement with a bola line or lines or with each other. Two or more of such fingers may be used and may be regularly or irregularly spaced apart on a bola body. A bola with such bodies includes lines which are connected to the other bodies. In one particular embodiment of a bola body, according to the present invention, the body has an irregular shape with a bottom rectangular portion and a top pyramid portion forming a nose. A plurality of fingers is extended from the pyramidal top portion with one finger extended up and away from each of four corners of the top portion. Such a bola body tends to be initially oriented with its nose and fingers against an object being snared since the body is pulled nose first when a bola line is secured at the tip of the pyramidal portion of the bola body. With such a bola, an unwrapping bola body can slip around a target member so that two of the rod-shaped fingers catch a bola line and guide it into an area or crook between the fingers and a side of the top pyramidal portion of the bola body. Tension on the bola line maintains the line in the crook and tends to press the fingers against the unwrapped target member to stabilize the wrapping of the line about the target member. With such a bola, it is difficult for two or more lines unwrapping in different directions to move past one another without being forced together by line tension. Also, the fingers of such bola bodies may hook and hold each other. The fingers may also hook or entangle some object on or portion of the target member. A probable known target member has known dimensions and shapes so that the bola may be sized and configured to reliably snare such a known target. The bolas can be optimally sized, fashioned, and configured to contact and hold a probable target of known size, dimension, and shape.

A compressor with no moving parts in the traditional sense having a housing having an inlet end allowing a low pressure fluid to enter and an outlet end allowing a high pressure fluid to exit is described. Within the compressor housing is at least one compression stage to increase the pressure of the fluid within the housing. The compression stage has a quantity of magnetic powder within the housing, is supported by a screen that allows passage of the fluid, and a coil for selectively providing a magnetic field across the magnetic powder such that when the magnetic field is not present the individual particles of the powder are separated allowing the fluid to flow through the powder and when the magnetic field is present the individual particles of the powder pack together causing the powder mass to expand preventing the fluid from flowing through the powder and causing a pressure pulse to compress the fluid.

An electromagnetic brake/clutch device includes a drive shaft supported by at least one bearing for transmitting torque, a housing, affixed to prevent its rotation, surrounding the drive shaft, and an electromagnetically activated device within the housing to selectively prevent and allow rotation of the drive shaft. The electromagnetically activated device includes a plurality of cammed rollers to prevent counter-clockwise rotation of the drive shaft. The drive shaft includes a circumferential disk and the housing includes a reaction ring for engagement with the plurality of cammed rollers. The plurality of cammed rollers are released from engagement with the circumferential disk and the reaction ring by a plurality of tripping mechanisms within the housing. The tripping action uses the locking force to act as a release force merely by changing the boundary conditions of the roller interface angles. The tripping mechanisms include trippers for disengaging the plurality of cammed rollers and an anvil shaped portion for providing lateral movement of the trippers. The plurality of cammed rollers is preloaded to engagement with the circumferential disk and reaction ring by a spring, and is located with respect to an adjacent tripping mechanism with another spring. THE DOWN, RELEASE, AND DEPLOYMENT OF THE RADARSAT SAR ANTENNA c32
G. S. Bush *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 7 p Sponsored by Canadian Space Agency (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The Canadian RADARSAT remote sensing satellite is described. RADARSAT employs a Synthetic Aperture Radar (SAR) instrument with a very flexible set of operating capabilities that include selectable swath widths, ground incidence angle and resolution. The SAR antenna is a 15 by 1.5 m slotted waveguide planar array with a mass of 730 kg. This SAR antenna is able to alter its beam pointing angle to anywhere within a 500 km Earth ground track with either a wide or narrow swath, at ground incidence angles from 20 to 49 degrees. The antenna and spacecraft requirements associated with the tie down and deployment activities for RADARSAT are described. System tradeoffs involved with the selection of the design approach adopted for the tie down assemblies and extendible support structure are discussed. The selected mechanisms and their important components are provided. ESA

METAL BAND DRIVES IN SPACECRAFT MECHANISMS
Daryl Maus *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

Band drives, rack and pinion gears, and bell cranks are compared for effectiveness. Band drive issues are discussed including materials, bend radius, fabrication, attachment and reliability. Mechanisms illustrating practical applications of band drives are shown. Metal band drives offer several advantages including: small size, high efficiency, low contamination and long life. They provide solutions of problems involving variable output from a constant input. Several properties of a cobalt-chromium-nickel alloy, named Elgiloy are presented. Elgiloy is found to be an excellent choice for the drive band. ESA

MICRO-GRAVITY COMPATIBLE DRIVE (MGCD)
Bhoj Nagwaney, T. K. Lien (Norges Tekniske Hoegskole, Trondheim.), N. Wavre (ETEL S.A., Motiers, Switzerland.), and A. Robinson (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The Microgravity Compatible Drive (MGCD) is one of the most demanding subsystems of the future manipulator systems on orbit such as Equipment Manipulator And Transportation System (EMATS). It is developed to provide a linear motion of EMATS in the z-axis of the Columbus attached module and/or the pressurized module of the FreeFlyer. A breadboard model of a MGCD was designed, manufactured and tested. The MGCD consists of the components which are typical for any joint/limb of a manipulator or other drive systems. The approach followed was to make a selection of appropriate technologies and try to reduce the disturbances right away at their sources of generation. The test results in the time domain were found to be within the micro-g requirements, however, the target levels were exceeded in the frequency domain. The main source of disturbances was found to be the harmonic reduction gear which also excited different modes of the structure. ESA

LOW NOISE ELECTRIC MOTOR c33
E. Favre, M. Correvon, and M. A. P. Verain (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 7 p (For primary document see N94-23985 06-37)
(Contract ESTEC-9239/90/NL/PP)
Copyright Avail: CASI HC A02/MF A04

The purpose is to point out a motor/driver assembly which has a so called 'low noise' behavior, minimizing the noise and vibrations generated to the external environment. Vibrations created by an electric motor may be harmful to the experiments made in the vicinity. For the motor, noise and vibrations are involved either by magnetic parasitic forces or by non-controlled mechanical tolerances. The importance of the perturbations depends on the amplitude of the parasitic forces and on the natural frequencies of the mechanical parts subject to these pulsating constraints. The study is focussed on the available motor/driver design opportunities leading to a reduction of the amplitude of these forces. The cost in weight and volume involved by a low noise design is pointed out for a given 0.5 Nm/2500 rpm application. ESA

NEW TRIBOCOATING COMBINATION FOR VACUUM OPERATION
M. Maillat and H. E. Hintermann *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

A new coating combination to obtain low wear, a low and stable friction coefficient in a vacuum and dry air, as well as in humid air is proposed. The main properties of MoS_2, TiC, amorphous carbon a-C:H, and diamond like carbon coatings are summarized. Examples of tribological behavior of a-C:H coatings from different suppliers are presented. The effect of humidity on friction of a-C:H is discussed. These differences show that a-C:H coatings, which are potentially very interesting, should be investigated in order to be space qualified for future tribological problems. Diamond like carbon can be an excellent sliding coating for space applications. ESA

TRIBOLOGICAL BEHAVIOUR OF FLUORINATED RESINS AND POLYIMIDE RESINS SLIDING OVER A METALLIC SURFACE IN LIQUID NITROGEN
Jean-Luc Bozet and Rene Gras (Institut Superieur des Materiaux et de la Construction Mecanique, Saint-Ouen, France.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

In a cryogenic fluid, the sliding of polymers over a metallic surface is governed by adhesion more than by deformation phenomena. Polyimide resins and fluorinated resins submerged into a cryogenic fluid exhibit a noticeable increase of hardness which induces a decrease of the friction coefficient and of the wear rate compared to a sliding process performed in ambient air. The decrease of wear and friction coefficient is linked to adhesive and deformation phenomena. For fluorinated resins a cold flow is observed. This behavior is illustrated and quantified from test results. Polychlorotrifluorethylene and polyimide resins are characterized. ESA

TRIBOLOGICAL CHARACTERISTICS OF BALL BEARINGS LUBRICATED WITH A SPUTTERED MOLYBDENUM DISULPHIDE FILM IN A VACUUM UNDER A HIGH THRUST LOAD
M. Suzuki and M. Nishimura *In* ESA, The Fifth European Space

Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

Ball bearing tests performed in vacumm under a contact stress of 2.3 GPa are reported. The bearings were lubricated with an MoS2 sputtered film and contained in a polytetrafluoroethylene cage. After the MoS2 film failure, frictional torque increased drastically, however, no seizure occurred. In a test using a bearing without the MoS2 coating, transfer film formed from the cage proved to be an effective lubricant under a contact stress of 2.1 GPa. An X-ray photoelectron spectroscopy analysis of the balls revealed the presence of Mo and metal fluoride on the ball surfaces.

THE TRIBOLOGY OF SOME MoS2-LUBRICATED ENGINEERING CERAMICS
J. M. Cunningham, M. J. Anderson, S. G. Gould, and E. W. Roberts *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The tribological properties of ceramics involving friction and wear slide tests in both air and vacuum were investigated. Tests with and without lubrication were performed. The ceramics tested were silicon nitride, silicon carbide, titanium carbide, titanium nitride and zirconia. The study demonstrated that, in general, unlubricated ceramics yield high friction in both air and vacuum. MoS2 lubricated ceramics give low friction in vacuum, their friction and wear properties are compared with that of MoS2 coated bearing steels. The results indicate that MoS2 lubricated ceramic bearings should prove superior to similarly coated steel bearings in terms of reduced torque and prolonged low friction lifetime. This is particularly attractive to the space industry.

THE COLUMBUS SOLAR ARRAY MECHANISMS **c44**
R. Zwanenburg *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The concepts and the development efforts of the new and very large rigid panel solar array for the ESA Polar Platform are summarized. The large array size required the development of new mechanical systems to support and deploy the array panels. The solar array is fixed to the spacecraft with 16 hold down points. Flexibility in the hold down connections is incorporated for load distribution. A continuous Kevlar cable loop was developed to cope with the increased preloads. The panels are deployed by a mechanism of supporting beams and a motorized cable system. An engineering model of this panel deployment mechanism was built and tested.
ESA

PRIMARY DEPLOYMENT MECHANISM FOR THE EUROPEAN POLAR PLATFORM **c18**
S. C. Burgess and M. E. Humphries *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The principal mechanism design requirements of the Primary Deployment Mechanism (PDM) are summarized. The solution developed to meet these requirements is presented. The PDM is responsible for deploying the solar array and for maintaining its alignment and power transfer for a minimum of four years. The PDM contains a 3.8 m arm structure with three deployable powered hinges. The powered hinges contain a patented actuation and locking system that is reliable and simple to test. The PDM also contains two passive hinges that are aligned by spring compression forces. The passive hinges have a torsional stiffness that enables the PDM to withstand enforced displacements during launch and they also reduce shock loads at the end of deployment of each hinge.
ESA

N94-23996# Dornier System G.m.b.H., Friedrichshafen (Germany).
INVESTIGATIONS INTO DEPLOYMENT COMPLICATIONS OF THE ERS-1 SAR ANTENNA **c32**
R. Barho *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 4 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

The Synthetic Aperture Radar (SAR) antenna is an important part of the first European Remote Sensing Satellite (ERS-1). In deployed configuration it consists of a 10 by 1 m planar array, divided into a 5 single panel arrangement. The results of the investigations and tests on antenna and component level to find out the reason of this deployment hindrance of the ERS-1 SAR antenna are presented. Test results and corrective actions for the ERS-1 flight model resulted in a successful deployment in space and with the metal oxide semiconductor powder treatment of the rubber surfaces as small hardware modification for ERS-2. 'Sticking' or 'sucking' phenomena were detected on a rubber material. To avoid similar problems in other projects it is recommended to close the gap of knowledge concerning this phenomena by a respective test program, or at least to verify a long time storage effect by respective component tests.
ESA

N94-23997# Hughes Aircraft Co., Los Angeles, CA. Space and Communications Group.
LOW MELTING TEMPERATURE ALLOY DEPLOYMENT MECHANISM
M. J. Madden *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

A concept of a low melting temperature alloy deployment mechanism is presented. Conventional dimethyl-silicone fluid damped mechanisms are reviewed. Design fundamentals of the melting alloy mechanism are introduced. Benefits of the new over the old are compared. This mechanism is promising, and its use may soon be recommended. A demonstration unit is powered-up to visually illustrate the deployment. This technology is proposed in the following applications: a light payload retention latch and release device; a method to relieve large misalignments between shuttle and payload; and zero backlash latch mechanisms.
ESA

N94-23998# Dornier System G.m.b.H., Friedrichshafen (Germany).
DEVELOPMENT STEPS ON THE BASIS OF TEST WITH THE LOCSTAR REFLECTOR DEPLOYMENT MECHANISM
I. Koeker and C.-C. Etzler *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

The development phase of the deployment mechanisms through various tests on various test devices is presented. The test results and the step by step process to recognize the reasons for the unexpected behavior and their elimination are summarized. The deployment mechanisms for two 3 by 3 m parabolic reflectors, to be mounted on the LOCSTAR satellite, allow a deployment of the reflectors from storage for launch and their arresting with high accuracy and high stiffness in operating configuration in orbit. The results of the tests showed that the temperature drift of the deployment angle was out of the specification. In order to achieve thermal stability, the materials of the latching equipment components have to be chosen carefully. Thermostability components like Carbon Fiber Reinforced Plastics (CFRP) do not prevent a change of length of the surrounding components. For thermoelastic analysis CFRP components as well as the materials of the surrounding construction have to be taken into account. The mechanical coupling restraints of connected parts have an influence on the thermal stability of the deployment mechanism. To prevent the angular movement, the thermal extension and elastic deformation due to the coupling restraint has to be avoided. A single degree of freedom in lateral direction has to be available.

N94-23999# Max-Planck-Inst. fuer Aeronomie, Katlenburg-Lindau (Germany).
ULTRA-CLEAN HIGH-PRECISION MECHANISMS FOR THE SUMER EUV SPECTROMETER ON SOHO
W. Engelhardt and H. Hartwig *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 4 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

The Solar Ultraviolet Measurements of Emitted Radiation in the Extreme Ultraviolet (SUMER EUV) spectrometer on Solar and Heliospheric

Observatory (Soho) contains a total of eight mechanisms; two of them with redundant drives. The design and lubrication concepts, the performance data and some test results for the following mechanisms are presented: the pointing mechanism that rotates the off axis paraboloid telescope mirror about its focal point 1300 mm away with a resolution of less than 0.5 arcsec; the aperture cover with a hinge drive of varying reduction ratio able to combine a short closing time with a high final closing force, where a redundant release mechanism based on a sealed paraffin actuator was implemented; the focussing platform mechanism with redundant ball lead screw drives and both static and dynamic balancing. The major design drivers for these mechansims are: the stringent cleanliness requirements mandatory for this class of EUV instruments; the nominal design lifetime of two years of operation in the interplanetary space environment. ESA

PERISCOPE MECHANISM FOR SWAN INSTRUMENT
Heikki Huomo, Heikki Hannula, and Kai Viherkanto *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p Sponsored by Technology Development Center and Technical Research Centre of Finland Prepared incooperation with CNRS, Verrieres le Buisson, France and Finnish Meteorological Inst., Helsinki, Finland (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

The Solar Wind Anisotropies (SWAN) instrument is a Lyman-a imaging spectrometer on board the Solar and Heliospheric Observatory (Soho) spacecraft. The SWAN instrument comprises two identical sensor units and an electronics unit. The total weight of the instrument is about 14 kg. Both sensor units have a two axis periscope mechanism. This allows the SWAN instrument to make a full sky map of the Lyman-a intensity at any given time. The SWAN instrument mechanism and the components critical to the mechanism performance are described. The scientific and budgetary requirements for the mechanism are summarized. Actual construction and the component level performance testing is discussed. The tests performed for the mechanism subsystem are discussed. Concluding remarks are given. ESA

N94-24001# Saab-Space A.B., Linkoeping (Sweden).
OPENING MECHANISM FOR ISO/CVV COVER RELEASE
Torbjoern Andersson *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The cover to the Infrared Space Observatory/Cryostatic Vacuum Vessel (ISO/CVV) will be released and ejected after several days in orbit. The specific need for a clean and reliable low temperature operation and the possibility of using a partly recurrent design from clamp bands used for spacecraft release were identified. A new developed opening mechanism is used instead of the conventional connecting bolt and pyrotechnic bolt cutter. The design is a mechanism which connects the two clamp band halves together. The mechanism provides an opening moment also for the worst case friction expected in operation. The tensioning forces from the two clamp band halves are reduced in several steps so that they could be handled by a small shaft which prevents the mechanism from opening in locked position. The initiation of the opening is made by an electromagnet which pulls the shaft. The surface treatment used for the mechanism is titanium nitride and the limited lubrication is made by molybdenum disulfide which is burnished into the contact surface. The mechanism functioning was verified. ESA

WIDTH MODULATOR MECHANISM FOR SPECTROMETER ENTRANCE SLITS
G. Mondello, G. Basile, G. Cherubini, and N. Tonetti *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 7 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The development for the mechanisms of the Ultraviolet Coronograph Spectrometer (UVCS) to study the ultraviolet and visible light spectrums of the solar corona is reported. The UVCS was designed to be integrated on the Solar and Heliospheric Observatory (Soho). The modulation mechanism has the purpose of changing the field of view of the spectrometers entrance beam by adjusting its width through the translation of one edge defining the entrance slit. The mechanism is required to maintain a stable configuration during observations, to smoothly modulate the edge position in the range between 10 to 355 micrometers, and to ensure repeatability and stability in slit edge positioning. The investigated solution is presented with spotlights on several design aspects like flexural element, bearings, lubrication system, and motion laws under the specific constraints. A development model is under evaluation and a comparison between required accuracies in a space environment and measured accuracies in 1 g environment before and after environmental testing is given. ESA

The GRADIO instrument is designed to measure the Earth gravity field, using accelerometers, onboard the Aristoteles (Applications and Research Involving Space Techniques for the Observation of the Earth's fields from Low Earth orbit Spacecraft) satellite. An overview of different concepts that were generated during predevelopment activities for the Aristoteles calibration device is given. The final concept, which is a rectilinear movement system based on elastic elements, is described. The generation of the concept was based on fundamentals of mechanical design, such as degrees of freedom, and knowledge on the behavior of elastic elements. The concept can be adapted to other applications. Larger amplitudes are possible and better results on decenter are feasible. More specific applications are precision linear guides for optical components and sensitive accelerometers. The high lateral stiffness facilitates clamping of the system and makes it useful for space applications. ESA

In the reference scenario of the Rosetta comet nucleus sample return mission, the sample acquisition system is to be mounted on the comet lander, together with the anchoring subsystem. Its tasks are to anchor the lander to the comet, acquire three kinds of cometary samples and transfer them to the Earth return capsule. The sample acquisition system comprises mainly: a coring tool, a shovelling tool, an external sample cutting device, a handling arm, the associated three anchoring systems, and the control electronics. The design of the prototype corer, surface sampling tool, and anchor for testing at cryogenic temperatures, in various materials representing cometary soil, are presented. Preliminary test results are discussed. ESA

SILEX, an experimental inter orbit communication system, is described. It makes use of a laser beam as transmission support between a so called Low Earth Orbit (LEO) terminal, to be installed on SPOT 4, and a so called Geostationary Orbit (GEO) terminal, to be installed on Artemis. For laser beam stability reasons, the laser source, the receiver, the collecting telescope, and other equipment must be monolithically grouped in a carrier structure which, in turn, is mounted on a coarse pointing mechanism making up the whole aerial. The total mass of this assembly can reach 70 to 90 kg and must be firmly held down during launch in order to withstand the quasistatic and dynamic loads. The stiffness requirement for the launch locking devices is up to 130 Hz in the case of the SILEX program. The mechanical configuration and the design requirements of the launch locking devices are discussed. ESA

THERMAL VACUUM PERFORMANCE OF CYCLOID AND HARMONIC GEARBOXES WITH SOLID (MoS2) AND LIQUID (BRAYCOTE 601) LUBRICATION
S. Gill, D. J. Forster, and R. A. Rowntree *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The tribological performance of cycloid and harmonic gearboxes for spacecraft applications is investigated. The tests performed on high torque capacity gearboxes, in an in-vacuo test facility, are reported and the test facility is described. The purpose of the tests was to research the efficiency of dry and grease lubricated gearboxes in vacuo. Although the harmonic drive was superior in terms of efficiency over the cycloid gearbox, the wear of the gear teeth was evident after only a short test duration, whether grease or dry lubrication was used. A full scale life test of any design incorporating a novel gearbox is recommended to prove the long term durability with space lubricants in the space environment. ESA

Copyright Avail: CASI HC A02/MF A04

The tribological tests performed on three (two oil-based and one grease) selected wet lubricants are reported. The tests were carried out on a vacuum friction test bench which allows the control of the main contact parameters: speed, load, kinematics, atmosphere. Variations of physical properties versus temperature and pressure are taken into account in the test results analysis through a rheological characterization performed on the lubricants tested. The tribological tests under vacuum show that the supply conditions depend on the properties of the liquid and on imposed conditions. When the lubricant supply is insufficient, the liquid film is broken and risks of direct interaction between the first bodies appear. In vacuum conditions, this is a redhibitory defect. The study is directed towards the identification of phenomena that cause a protective third body to form in space conditions. ESA

IN-VACUUM PERFORMANCE OF FOMBLIN Z25-LUBRICATED, 52100 STEEL BEARINGS WITH TIC-COATED BALLS
S. Gill, W. B. Price, R. A. Rowntree, H. J. Boving (Swiss Center for Electronics and Microtechnology, Inc., Neuchatel.), and H.-E. Hintermann (Swiss Center for Electronics and Microtechnology, Inc., Neuchatel.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The effectiveness of TiC coated AISI 440C stainless steel balls in preventing the in vacuo degradation of Fomblin Z25 oil was evaluated. The balls were incorporated into SAE 52100 steel 20 mm bore angular contact ball bearings, and run in a vacuum bearing test facility. One pair of bearings was run at 200 rpm for 1.4 x 10(exp 8) revolutions, whilst the second pair performed 9 x 10(exp 8) revolutions at 1400 rpm. At 200 rpm, there was also a significant increase brought by the TiC coating to the life expectancy of Fomblin Z25 oil, with no evidence of lubricant degradation after 1.4 x 10(exp 8) revolutions. The balls remained in pristine condition at the end of the test, with no evidence of damage to the TiC coating. ESA

A design study of the mechanism of an infrared atmospheric sounder is presented. The instrument is designed to measure the emission spectrum of the atmosphere in the 3.4 to 15.5 micrometers range. This sounder, based on the interferometric principle, is composed of a scan unit, an interferometer, and detectors. The mission requirements and the resulting specifications of the mechanism are expressed. A ball bearings and flexural pins solution and a magnetic bearings solution are compared. The selection is based on the dynamic performance, the overall dimensions, the reliability, and the lifetime of the two solutions. The selected design of the scan system is described. Future work for the development and the qualification of this mechanism is suggested. ESA

AN EARTH OBSERVATION TELESCOPE REFOCUSING MECHANISM
M. Lavadoux and J. F. Patin (Aerospatiale, Cannes, France.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

The refocusing mechanism developed for an observation satellite is described. The mechanism fulfills the following functions: it holds the focus lens in the nominal flight position throughout the launch phase; and it acquires and maintains the focus lens position during observation to compensate for dimensional variations in the telescope in orbit. When the telescope is in orbit, the mechanism is capable of moving the lens in steps of approximately 20 microns and positioning it accurately both in tilt and lateral offset of its center. The main difficulties encountered in developing the product are presented. The mechanism was validated by several tests. ESA

DATA RELAY SYSTEM SATELLITE: THE DEVELOPMENT OF AN ANTENNA POINTING MECHANISM FOR THE INTER-ORBIT LINK ANTENNA
Laurent Curbillon and Gilles Labruyere (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 7 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The feasibility of an Antenna Pointing Mechanism (APM) suited to the interorbit link antenna of a Data Relay System (DRS) spacecraft was investigated. The APM mission, requirements, design of the mechanism, breadboard model development, and available test results are summarized. The APM concept selected is based on a large motorized gimbal, which is built around the antenna feed. The main components of the mechanism are dry lubricated, solid preloaded, angular contact ball bearings, stepper motors, and low backlash speed reducers. The gimbal mechanism holds a 1 m long carbon fiber reinforced plastic arm at the tip of which arm the reflector is attached. ESA

INTER ORBIT LINK ANTENNA POINTING MECHANISMS DESIGN USING STANDARD ACTUATORS
D. Buvat, M. Souliac, B. Bruneau, and G. Muller *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 12 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A03/MF A04

The interorbit link Antenna Pointing Mechanism (APM) is discussed. The steps leading to the choice of superimposed actuators with their rotation axis crossing at focus are summarized. The APM actuators are space qualified stepper motors using harmonic drive reducers with large reduction ratios without backlash. These actuators are open loop current controlled in microstep mode and equipped with redundant windings. Large annular ball bearings were selected for the gimbal first articulation, to ensure enough stiffness and to withstand the launch loads within the small clearance allowed around the antenna feed volume. The gimbal second articulation is achieved by two opposite gimbal pairs. Wet lubrication was selected for both actuators and gimbal ball bearings. Required antenna reflector motion is achieved without singularity, using quasi-linear and high reduction ratios, within allowed APM volume. ESA

NUMERICAL SIMULATION OF ULYSSES NUTATION c18
C. GarciaMarirrodriga, J. Zeischka (LMS International, Leuven, Belgium.), and E. C. Boslooper (Fokker Space and Systems, Amsterdam, Netherlands.) *In its* The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 8 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The in-orbit instability of the Ulysses spacecraft was numerically simulated. The thermal excitation from the solar flux, the flexible axial boom, and the deployment mechanism were modeled and analyzed. In order to model a non-isolated mechanical system, the link between thermal, structural, and multibody dynamics packages is considered. The simulation shows that the nutation build-up was originated by the solar input on the axial boom coupled with the nutational frequency of the spacecraft. The results agree with the observed behavior. ESA

The results of the Olympus satellite vibration monitoring experiment are analyzed. The in-orbit responses arising from various sources were identified and ranked. Methods of automatic identification and classification were taken into account. The following sources were considered: thrusters, reaction wheels and momentum wheels, waveguide switches, solar array drive mechanisms, and the antenna pointing mechanisms. The primary aim was to quantify the vibration environment and establish a database of the vibration characteristics of the onboard equipment. A secondary purpose was to enable the long term condition monitoring of the equipment. The structural modeling applied to estimate the signal characteristics at the mechanism location is described. ESA

MICROWELDING DUE TO RANDOM VIBRATION
D. Coquelet and G. Gallay *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The non-actuation of the latching of the direct broadcast satellite antenna and the boom deployment mechanisms are discussed. The aim is to show the logic that took place to solve the problem of the microwelding of contact areas due to random vibration which is the cause of the jamming of the device and to propose a feedback solution. The on site statements and the visual inspection which took place during the test campaign lead to the following conclusions: the blocking of the latch was probably initiated by microwelding or surface bonding evidenced by metal transfer; the system recovers its nominal performance once the system is manually activated due to shearing of the microwelding spots; and the failure occurs only during dynamic vibration once a threshold level is passed over giving sufficient energy to initiate the surface bonding. ESA

THE DEVELOPMENT OF THE HERA TEST FACILITY (HTF) c14

Aad P. Eggers *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 7 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The Hermes Robot Arm (HERA) Test Facility (HTP) is a two axis zero gravity facility used for HERA integration and testing. The current facility concept is the result of system level trade studies which showed its potential advantages over the standard flat floor concept. The advantage is that the test results can be used to verify computer models. The servosupports introduce disturbance forces into the arm movement. The servosupports simulate a zero gravity environment by eliminating the effects of gravity on the arm with air bearings and minimizing the dynamic variables introduced by the drive and leveling subsystems. The weight components of the arm are counteracted by constant support forces. A facility to demonstrate the practical application of the servosupport concept and minimize the technical risk of implementing a new complex system is presented. ESA

A COMBINED EARTH SCANNER AND MOMENTUM WHEEL FOR ATTITUDE DETERMINATION AND CONTROL OF SMALL SPACECRAFT
c18
Bill Bialke *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The design ground rules, the tradeoff analyses, and the performance results of a modular momentum/reaction wheel with an integral conical earth scanner are reported. The aim of the project was to satisfy the stringent cost and power requirements of small satellites. The momentum wheel provides momentum bias and control torques about the pitch axis of a spacecraft. An angled scan mirror coupled to the rotating shaft of the momentum wheel provides a conical scan of the field of view of an infrared sensor to provide pitch and roll attitude information. By using the same motor and bearings for the momentum wheel and earth scanner, the overall power consumption is reduced and the system reliability is enhanced. ESA

PRECISION DISPLACEMENT MECHANISM (PDM)
J. I. Bueno, F. delCampo, and P. Coste (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

A mechanism designed to fulfill the requirements of the Precision Displacement Mechanism (PDM) for the Far Infrared and Submillimeter Space Telescope (FIRST) antenna is described. The PDM function is to perform the fine adjustment of the position of the main reflector folding panels. The main requirement for such a mechanism was to achieve small displacements without backlash, while having a high stiffness, in a cryogenic environment and being thermally stable. The PDM design is based on a structure deformed by a linear actuator and is capable of generating submicron steps. The structure deformation provides the necessary reduction to the output of the linear actuator. A breadboard model of this mechanism was built and tested. The results show that the PDM meets the expected performance. ESA

AN OPENING MECHANISM FOR THE SCIENTIFIC AIRLOCK OUTER HATCH
C. Compostizo and I. deOlazabal *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

The hatch mechanisms of the scientific airlock, one of the Attached Pressurized Module (APM) subsystems, are described. The scientific airlock consists of an enclosed cylindrical volume that may be opened alternatively to the environments of space and module atmosphere. Closure of the volume is obtained by an inner and outer hatch. Between all the airlock mechanisms, the hinge and opening mechanism of the outer hatch can be highlighted. The hatch is closed from the inside and sealed under pressure loading, but opening in opposite direction. This approach was made feasible by defining an elliptical shape for the outer opening and the outer hatch.

Such a geometry allows the minor axis of the hatch to pass through the major axis of the opening. ESA

THE DEVELOPMENT OF THE SOHO SUMER MECHANISMS

W. Engelhardt, H. Hartwig, and K. Poser *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 2 p (For primary document see N94-23985 06-37)

Copyright Avail: CASI HC A01/MF A04

The reliability of the Solar Ultraviolet Measurements of Emitted Radiation (SUMER) mechanisms, for the Extreme Ultraviolet (EUV) spectrometer, are discussed. These mechanisms are designed to adjust the optical elements of the SUMER EUV spectrometer to the needs of the varying observational modes. These mechanisms were designed to keep the development and qualification effort for their components under control: all of them make use of drive trains where stepper motors are directly coupled to ball lead screws and translations are supported by ball bushings. One of the main problems of SUMER is its sensitivity to contamination, especially to organic outgassing products which are rapidly polymerized on the optical surfaces under UV illumination. Efforts to develop custom versions of critical components were made. ESA

VISCOUS ROTARY DAMPER

F. Koller, T. Nitschko, and G. Labruyere (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)

Copyright Avail: CASI HC A02/MF A04

Directly driven viscous rotary dampers, for limiting deployment rates of spring driven mechanisms, are presented. They provide sufficient resistive torque without mass and reliability penalties associated with high ratio gears as required for equivalent devices such as centrifugal brakes or eddy current dampers. This type of damper necessitates application of highly viscous silicone oil as the working fluid. Contamination associated with leakage of the damper is the key problem with respect to the viscous rotary damper application. The device presented is designed for temperature ranges for survival and for operation of -150 to +150 C as well as -30 to +50 C, respectively. Sample tests of the shaft seals proved leak tightness in case of loads and environmental conditions to be expected in course of the damper life cycle. This damper concept seems promising for future application. ESA

DEVELOPMENT OF A LOW-TEMPERATURE GEAR MOTOR (LOG)

M. Schmid *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 4 p (For primary document see N94-23985 06-37)

Copyright Avail: CASI HC A01/MF A04

A precision actuator designed to exceed the common temperature range for space actuators, down to values in the range of minus 160 C, is described. The actuator covers a wide range of potential space applications such as antenna pointing, solar array rotation, mirror adjustment or deployment. One of the main features of the actuator, consisting of a rotary disc stepper motor combined with a harmonic drive gear stage, is its good low temperature performance required in infrared satellites or experiments with long nonoperating times in cold space. The low temperature gear motor provides a peak output torque in the 10 Nm range and microstepping is possible. ESA

AN ANALYTICAL ULTRA-HIGH VACUUM TRIBOMETER FOR SOLID LUBRICANT STUDIES

T. LeMogne, Y. Chevallier, C. Donnet, and J. M. Martin *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p Sponsored by Region of Rhone-Alpes (For primary document see N94-23985 06-37)

Copyright Avail: CASI HC A01/MF A04

An analytical ultrahigh vacuum tribometer, allowing complete tribochemistry studies of various kinds of materials, was developed in view of ultrahigh vacuum or a controlled partial pressure of O2, H2, or H2O. The main advantage of this device is the direct coupling of tribological/analytical characterization with the possibility to carry out surface treatments. This apparatus is suitable for studying fundamentals in friction, correlated with a fine description of the friction induced chemical modifications of the tested materials. MoS2 coatings were sputter deposited onto silicon substrates. An in situ x ray photoelectron spectroscopy characterization of the first growth stage of the interface indicates a chemical reaction between sulphur and silicon, whereas the growing film is constituted of pure, nearly stoichiometric MoS2. The tribological behavior of a 60 nm thick MoS2 coating in situ prepared is characterized by a low value of the friction coefficient during the first 90 cycles. ESA

A NOVEL ROTARY ACTUATOR FOR SPACECRAFT

P. Alan Jones, T. Jeffrey Harvey, and Scott F. Tibbitts (Starsys Research Corp., Boulder, CO.) *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p (For primary document see N94-23985 06-37)

Copyright Avail: CASI HC A01/MF A04

The design, development and testing of a new rotary actuator model, the AEC Able Engineering (ABLE) Repeatable Rotary Actuator (ARRA) are presented. The ARRA operates under a wide range of both torque and rotation angle. The ARRA system allows the torque and rotation of an individual actuator to be tailored to the specific mission requirements by modification of a single feature on just one part. The ARRA employs a high output parraffin linear actuator to supply linear motion that is converted to rotary motion by means of a tailorable helix cam. The use of a tailorable helix cam allows for the inclusion of multiple hingeline functions into a single mechanism. These functions include variable torque and stowed and deployed latching. This reliable device is one of the least costly controllable bidirectional units available. ESA

The Multipurpose Clamping Device (MCD), designed for in orbit positioning of payloads on the Space Station, is presented. The MCD provides a mechanical connection between the payload and a support structure. A redundant electrical connector can be integrated. The current design is dedicated to the need of one candidate payload for Space Station. The MCD can be scaled to any payload size and configuration and applied in any environment. The MCD design meets the given performance requirements and design criteria. The handling of MCD is simple and in addition MCD assists the robotics in positioning of payloads. The MCD guarantees a firm mechanical fixation and is backlash free. ESA

SENSORLESS, BRUSHLESS MOTOR TO DRIVE A SEALED FREON-AMMONIA PUMP c33
N. Wavre *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 5 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

The performances of a brushless motor, including sleeve losses and electronic performances, specially designed to drive a sealed pump wheel are presented. Low flow rate pumps with high efficiency are expected for both Columbus and Hermes. The challenge was to design a motor as short as a magnetic coupling and to assemble the rotor directly on the pump wheel subassembly. The use of a new sensorless driver technique was proposed. The electronic driver, the motor and the pump are remarkably efficient for a low power system (30W). The pump assembly is extremely compact. ESA

DESIGN AND PERFORMANCES OF ELECTROMAGNETIC INITIATORS FOR SPACE MECHANISMS: AN ALTERNATIVE TO PYROTECHNIC SYSTEM c33
N. Wavre *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 4 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A01/MF A04

The design of different actuators used for the Infrared Space Observatory (ISO) and Cassini mission Huygens titan space probe is presented. The electromagnetic actuator creates no particle debris and is reusable many times during system calibration and qualification. An electromagnetic initiator uses the reluctant principle with a preload spring and without magnets. The electromagnetic initiators were tested down to minus 168 C under vacuum conditions. An increase in release time can certainly be recognized between the test step at minus 140 C and minus 168 C, under the maximum radial load. Under this condition the release time was below 20 ms with the nominal current. Non-firing current of 1 amp is verified over the temperature range from ambient down to minus 168 C. ESA

The techniques employed to produce the high resolution, high accuracy encoder motor assembly are presented. The encoder motor assembly positions the primary mirror, which enables the radiometer to produce detailed images of the Earth from geosynchronous orbit by Geostationary Operational Environmental Satellite (GOES) VISSR Atmospheric Sounder (VAS). The major requirements, a description of the GOES VAS encoder motor assembly, and basic encoder motor construction are summarized. The optical, electronic, and mechanical techniques used to achieve the required resolution and accuracy, as well as the tests conducted on the flight qualification unit are presented. In orbit performance indicates no degradation in accuracy or performance of the GOES VAS encoder motors. ESA

The Deployment And Retraction Mechanism (DARM) is described. The mechanism was designed for the deployment and subsequent retraction of payloads. The DARM is a spring actuated mechanism. For its maneuvers, the DARM draws entirely on the elastic energy stored in a spiral spring. It carries out a limited number of sequences in accordance with the maximum energy stored in the spring. The recharge mechanism eliminates the problem of the limited range of sequences by recharging the spiral spring during idle times of the mechanism. The main characteristic of the recharge mechanism consists of the use of shape memory alloys, which enable thermal energy to be changed to mechanical energy. ESA

The ultrasensitive accelerometer package known as the PSDE (Payload and Spacecraft Demonstration and Experimentation program) Accelerometer Experiment, or 'PAX', is described. This package, which is onboard the Olympus telecommunication satellite, was designed to measure the minute disturbances caused by the operation of onboard equipment. This data was used to study the operating environment to be experienced by a highly sensitive laser based communications package called SILEX to be flown on the next generation of ESA telecommunications spacecraft, Artemis and DRS (Data Relay Satellite). A secondary purpose of PAX is to monitor the different mechanisms on board Olympus at intervals throughout their lifetime, in order to detect trends in performance. ESA

The design, development, commissioning, and evaluation of a Boundary Lubrication Accelerated Screening Tester (BLAST) are presented. BLAST was designed to provide a valid means of rapidly evaluating and ranking the boundary lubrication performance and degradation resistance of spacecraft liquid lubricants. BLAST is commissioned and capable of running accelerated tests on oils and greases in vacuum, and assessing the effects of differing coatings and substrates. Results to date gave a ranking directly comparable with that of real life tests. To date, more than 60 tests of differing space lubricants, bearing materials and surface treatments/coatings were performed. The benefits (or not) of new space lubricants and novel surface treatments/coatings are described. ESA

STATIC ADHESION IN PRELOADED CONTACTS SUBJECTED TO LONG-TERM VACUUM EXPOSURE
S. Gill and R. A. Rowntree *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

A facility, developed to support ESA missions and designed to investigate the sensitivity of material combinations to differing contact stress levels during long term exposure to vacuum conditions is described. The facility allows measurement of the static adhesion forces in vacuum. The materials investigated are of relevance to the mechanism designer, and the time periods under consideration are up to ten years. The results show that the possibility of static adhesion occurring in an interface which is not disturbed seems remote. ESA

AN ASSESSMENT OF SOLID LUBRICANT FILMS FOR USE IN HIGH TEMPERATURE SPACE APPLICATIONS
M. J. Anderson and E. W. Roberts *In* ESA, The Fifth European Space Mechanisms and Tribology Symposium Apr. 1993 6 p (For primary document see N94-23985 06-37)
Copyright Avail: CASI HC A02/MF A04

Solid lubricant coatings were applied to Inconel 600 substrates and evaluated under reciprocating sliding motion against unlubricated Inconel 600 pins. MoS2, Ag, WS2 and PS212 lubricants were applied. Tests were carried out in a nitrogen atmosphere at room temperature, 400C and 800C. It was found that materials which provided effective room temperature lubrication were less effective at high temperatures. The exception was a PS212 film (a composite of CaF2, BaF2, Ag, and Cr3C2 in a nickel cobalt matrix) which gave rise to lower friction as the temperature was increased above room temperature. Unlubricated Inconel versus unlubricated Inconel gave rise to high friction. The overall trend in the values of the peak friction coefficients is towards increased values with increasing temperature. Ceramic ball bearing cages lubricated with molybdenum disulphide (MoS2) were fabricated and tested. The materials tested were reaction bonded silicon carbide, reaction bonded silicon nitride, and sintered silicon nitride. The silicon carbide cages performed best in bearing tests. Reaction bonded silicon carbide, coated with sputter deposited MoS2 was also tested in sliding motion using a tribometer. Alkali etching the surface of the ceramic, to increase its porosity, led to a reduction in durability of the MoS2 lubricant film. Vacuum impregnation of the porous ceramic with powdered MoS2 prevented the subsequent layer of sputter deposited MoS2 from bonding to the ceramic substrate, and led to a catastrophic reduction in lubricant life. Advanced optical encoders for space applications are presented. In the field of angular position control, optical encoders show significant advantages in high resolution, and low weight and consumption. The reliability of the technology was demonstrated during a qualification program of a 21 bits encoder carried out especially for optoelectronical and ASIC (Application Specific Integrated Circuits) components. Designs and manufactures for spatializable encoders with resolutions up to 22 bits in a 127 mm diameter are under development. Their angular accuracy can reach +/- 2 arc sec. These encoders, both absolute and incremental, function in a range of temperature going from approximately -40C to +100C. An integrated cold redundancy is available from a diameter of 36 mm as well as an integrated partial control of functions. ESA

INTERNAL COMBUSTION ENGINE WITH A CENTRAL CRANKSHAFT AND INTEGRAL TANDEM ANNULAR PISTONS Patent [MOTEUR A COMBUSTION INTERNE A PISTONS ANNULAIRES, EN OPPOSITION ET SOLIDAIRES, ET A ARBRE CENTRAL]
Bernard Esparbes, inventor (to Micromedia Ltd.) 3 Aug. 1993 41 p In FRENCH
(CA-Patent-1-320-878; Int-Patent-Class-F02B-75/26; CTN-94-60928)
Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An internal combustion engine with tandem annular pistons and a central crankshaft is disclosed, based on that found in British patent 11027 of 11 May 1914. The piston block formed by the two pistons presents, at each axial extremity, a double axial skirt fitted with an outer crown forming the head of the piston as such, and an inner crown forming an inlet pump with a holding chamber radially located at the inside of the corresponding annular cylinder, in which the piston head delimits a combustion chamber. Radial fingers, crossing axial openings of the crankcase and radial holes of the piston block, have their inner radial ends engaged within wavy sinusoidal peripheral slots arranged in a bulging central portion of the central crankshaft set into rotation by alternating axial movements of the piston block. The admission of fuel or combustion sustaining gas is ensured axially by the extremities, valves, and openings in the end plates closing the holding chambers in which the inner crowns slide, fitted with valves to act as an inlet pump. The invention is particularly applicable to aircraft engines in view of the ease in which the shaft rotation can be adapted to such a use. CISTI

VIBRATIONAL POWER TRANSMISSION ANALYSIS OF MACHINERY INSTALLATIONS IN SHIPS WITH THE OBJECTIVE OF NOISE REDUCTION
B. J. Dobson, R. J. Pinnington, and R. G. White Jan. 1993 74 p
(ISVR-TR-216) Copyright Avail: Issuing Activity

Vibrational power transmission or 'power flow' analysis is a unifying concept which is used to study the many paths between machines and remote, noise radiating surfaces. The method may be employed analytically or experimentally to rank the many transmission paths from a machine in order to develop vibration control procedures. This may be done either at the design stage or to examine existing installations in order to reduce the vibrational power which ultimately reaches externally radiating surfaces. Theoretical methods are given here for studying power transmission from machinery sources through isolators, seating structures, pipes, structural elements and air-borne paths. Complementary experimental techniques for measuring vibrational power transmission through isolators, pipe work and structures are also described. The principal field of application described here is large machinery installations, and examples of laboratory scale studies are presented. Author

THERMOHYDRODYNAMIC ANALYSIS OF CRYOGENIC LIQUID TURBULENT FLOW FLUID FILM BEARINGS Annual Progress Report, 1 Jan. - 31 Dec. 1993
Luis San Andres Dec. 1993 137 p
(Grant NAG3-1434)
(NASA-CR-194869; NAS 1.26:194869) Avail: CASI HC A07/MF A02

A thermohydrodynamic analysis is presented and a computer code developed for prediction of the static and dynamic force response of hydrostatic journal bearings (HJB's), annular seals or damper bearing seals, and fixed arc pad bearings for cryogenic liquid applications. The study includes the most important flow characteristics found in cryogenic fluid

film bearings such as flow turbulence, fluid inertia, liquid compressibility and thermal effects. The analysis and computational model devised allow the determination of the flow field in cryogenic fluid film bearings along with the dynamic force coefficients for rotor-bearing stability analysis.

DESIGN OF A NEW HIGH-PERFORMANCE POINTING CONTROLLER FOR THE HUBBLE SPACE TELESCOPE Final Report, 3 Aug. 1992 - 3 Oct. 1993
C. D. Johnson Oct. 1993 99 p
(Contract NAS8-38609)
(NASA-CR-193891; NAS 1.26:193891; UAH-5-33020) Avail: CASI HC A05/MF A02

A new form of high-performance, disturbance-adaptive pointing controller for the Hubble Space Telescope (HST) is proposed. This new controller is all linear (constant gains) and can maintain accurate 'pointing' of the HST in the face of persistent randomly triggered uncertain, unmeasurable 'flapping' motions of the large attached solar array panels. Similar disturbances associated with antennas and other flexible appendages can also be accommodated. The effectiveness and practicality of the proposed new controller is demonstrated by a detailed design and simulation testing of one such controller for a planar-motion, fully nonlinear model of HST. The simulation results show a high degree of disturbance isolation and pointing stability.

WEAR REDUCTION IN CERAMIC BEARINGS BY SURFACE GENERATED PYROLYTIC CARBON CONTINUOUSLY REPLENISHED BY ETHYLENE GAS Final Report
J. L. Lauer and L. C. Davis 13 Dec. 1993 46 p Prepared in cooperation with General Motors Corp., Indianapolis, IN
(Contract NAS3-25950)
(NASA-CR-189214; NAS 1.26:189214; EDR-16732; AVSCOM-TR-92-C-032) Avail: CASI HC A03/MF A01

Sliding tests with a pin-on-disc tribometer and both sliding and rolling tests with a modified four-ball tester at bulk temperatures of about 500 C and contact pressures of about 2.2 GPa have demonstrated up to 80% reductions of friction and wear with silicon nitride surfaces when a stream of ethylene is directed into the conjunction region. The effects are even more pronounced when the ethylene is prenucleated by a flow over a coil of nichrome wire electrically heated to about 800 C and located about 30 cm upstream of the exit nozzle. Steel and Ni-plated steel are lubricated by this method even more efficiently at lower temperatures. Author (revised)

SEAL ASSEMBLY Patent
Jonathan G. Salt, inventor (to General Electric Co.), Ronald W. Korzun, inventor (to General Electric Co.), and David R. Abbott, inventor (to General Electric Co.) 19 Jan. 1993 25 p
(CA-Patent-163126888; Int-Patent-Class-F16J-15/44; Int-Patent-Class-F012C-7/28; CTN-94-60869) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A unitary annular seal structure is provided for attachment to a turbine nozzle in a gas turbine engine. The nozzle includes an annular platform disposed about a longitudinal axis of the engine. An annular array of vanes is secured to the platform. The seal structure includes an abradable annular seal member, a seal backing member, and a seal attachment ring. The ring includes an annular, radially extending, axially acting spring member positioned to cooperate with a plurality of radially extending tabs on the backing member. In use, the seal structure is positioned within a circular opening within the turbine nozzle. The nozzle includes a radially depending appendage formed as part of the nozzle platform. The spring member abuts one side of the appendage and the tabs are positioned to abut another side of the appendage for holding the annular spring member in gas sealing engagement with the appendage to thus provide a seal against gas leakage and to restrain the seal structure axially. The spring member and tabs comprise a radially slideable joint for the seal structure. To restrict circumferential motion of the structure, slots are formed in the appendage for receiving the tabs. The seal is easily replaced by bending the tabs and sliding the seal structure axially out of the nozzle. Differential thermal expansion is accommodated by the slideable seal arrangement.

FLUSH HEAD FASTENER Patent
Charles R. Smith, inventor (to Lockheed), Anthony E. Brindisi, inventor (to Lockheed), and Gerald W. Tyree, inventor (to Lockheed) 13 Oct. 1992 25 p
(CA-Patent-1308581; Int-Patent-Class-F16B-19/00; Int-Patent-Class-F16B-31/00; CTN-94-60872) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A flush head fastener is provided for joining two or more structural elements together, each element having a fastener hole with a recess for receiving the fastener head in communication with one surface of the structural elements. The fastener comprises a shank, a head joined to the shank, and a layer of non-resilient material permanently joined to and generally covering the entire top surface of the fastener. This layer is readily reconfigurable relative to the fastener head and the structural elements such that upon installation of the fastener in the hole, the layer can be reshaped by deformation, filling any gap between the head, the layer of material of the fastener, and the recessed end of the hole. Excess material above that needed to blend the layer of material into substantial conformity with the one surface of the structural elements can be easily removed. The fastener of the invention is capable of producing an aerodynamically smooth external surface, even when the surface is curved, and can be used with both metal and composite materials. The fastener produces no electrical discontinuities on the surface after installation. The fastener of the invention is especially intended for use in fastening aerodynamic surfaces of aircraft onto the underlying structural elements.

APPLICATION OF FAULT DETECTION TECHNIQUES TO SPIRAL BEVEL GEAR FATIGUE DATA
James J. Zakrajsek, Robert F. Handschuh (Army Research Lab., Cleveland, OH.), and Harry J. Decker (Army Research Lab., Cleveland, OH.) Jan. 1994 14 p Proposed for presentation at the 48th Mechanical Failures Prevention Group Meeting, Wakefield, MA, 19-21 Apr. 1994; sponsored by ONR
(RTOP 505-62-10; DA Proj. 1L1-62211-A-47-A)
(NASA-TM-106467; E-8333; NAS 1.15:106467; ARL-TR-345) Avail: CASI HC A03/MF A01

Results of applying a variety of gear fault detection techniques to experimental data is presented. A spiral bevel gear fatigue rig was used to initiate a naturally occurring fault and propagate the fault to a near catastrophic condition of the test gear pair. The spiral bevel gear fatigue test lasted a total of eighteen hours. At approximately five and a half hours into the test, the rig was stopped to inspect the gears for damage, at which time a small pit was identified on a tooth of the pinion. The test was then stopped an additional seven times throughout the rest of the test in order to observe and document the growth and propagation of the fault. The test was ended when a major portion of a pinion tooth broke off. A personal computer based diagnostic system was developed to obtain vibration data from the test rig, and to perform the on-line gear condition monitoring. A number of gear fault detection techniques, which use the signal average in both the time and frequency domain, were applied to the experimental data. Among the techniques investigated, two of the recently developed methods appeared to be the first to react to the start of tooth damage. These methods continued to react to the damage as the pitted area grew in size to cover approximately 75% of the face width of the pinion tooth. In addition, information gathered from one of the newer methods was found to be a good accumulative damage indicator. An unexpected result of the test showed that although the speed of the rig was held to within a band of six percent of the nominal speed, and the load within eighteen percent of nominal, the resulting speed and load variations substantially affected the performance of all of the gear fault detection techniques investigated.

This volume, Volume 2, of this Flex Bearing UUEC Final Report documents findings and data pertaining to Team B's tasks. Team B was organized as one of two sub-teams of the Unplanned/Unintended Event or Condition (UUEC) board established per InterOffice Memorandum (IOM) A100-FY93-072. Team A determined the cause of the unacceptable unbonds (referred to as 'heat-affect' unbonds), including the initial, light rust film, in the FSM #3 flex bearing was overheating of the Forward End Ring (FER) during cure, specifically in zone 8 of the mold. Team A's findings are documented in Volume 1 of this report. Team B developed flight rationale for existing bearings, based on absence or presence of an unpropitious unbond condition like that in FSM #3's flex bearing. Author (revised)

The Advanced Helicopter Electromagnetics (AHE) Industrial Associates Program has fruitfully completed its fourth year. Under the support of the AHE members and the joint effort of the research team, new and significant progress has been achieved in the year. Following the recommendations by the Advisory Task Force, the research effort is placed on more practical helicopter electromagnetic problems, such as HF antennas, composite materials, and antenna efficiencies. In this annual report, the main topics to be addressed include composite materials and antenna technology. The research work on each topic has been driven by the AHE consortium members' interests and needs. The remarkable achievements and progresses in each subject is reported respectively in individual sections of the report. The work in the area of composite materials includes: modeling of low conductivity composite materials by using Green's function approach; guidelines for composite material modeling by using the Green's function approach in the NEC code; development of 3-D volume mesh generator for modeling thick and volumetric dielectrics by using FD-TD method; modeling antenna elements mounted on a composite Comanche tail stabilizer; and antenna pattern control and efficiency estimate for a horn antenna loaded with composite dielectric materials. (Contract NASw-4435)
(NASA-CR-195549; NAS 1.26:195549) Avail: CASI HC A05/MF A01

The three year goal for this NASA Senior Design team is to design and build a walking autonomous robotic rover. The rover should be capable of rough terrain crossing, traversing human made obstacles (such as stairs and doors), and moving through human and robot occupied spaces without collision. The rover is also to evidence considerable decision making ability, navigation and path planning skills. These goals came from the concept that the robot should have the abilities of both a planetary rover and a hazardous waste site scout. Derived from text

INFLUENCE OF BACKUP BEARINGS AND SUPPORT STRUCTURE DYNAMICS ON THE BEHAVIOR OF ROTORS WITH ACTIVE SUPPORTS Semiannual Status Report
George T. Flowers Feb. 1994 9 p
(Grant NAG3-1507)
(NASA-CR-195106; NAS 1.26:195106) Avail: CASI HC A02/MF A01

Substantial progress has been made toward the goals of this research effort in the past six months. A simplified rotor model with a flexible shaft and backup bearings has been developed. The model is based upon the work of Ishii and Kirk. Parameter studies of the behavior of this model are currently being conducted. A simple rotor model which includes a flexible disk and bearings with clearance has been developed and the dynamics of the model investigated. The study consists of simulation work coupled with experimental verification. The work is documented in the attached paper. A rotor model based upon the T-501 engine has been developed which includes backup bearing effects. The dynamics of this model are currently being studied with the objective of verifying the conclusions obtained from the simpler models. Parallel simulation runs are being conducted using an ANSYS based finite element model of the T-501. Derived from text

(Contract NASw-4435)
(NASA-CR-195540; NAS 1.26:195540) Avail: CASI HC A06/MF A02

The University Space Research Association (USRA) requested the University of Minnesota Spacecraft Design Team to design a lunar transportation infrastructure. This task was a year long design effort culminating in a complete conceptual design and presentation at Johnson Space Center. The mission objective of the design group was to design a system of vehicles to bring a habitation module, cargo, and crew to the lunar surface from LEO and return either or both crew and cargo safely to LEO while emphasizing component commonality, reusability, and cost effectiveness. During the course of the design, the lunar transportation system (LTS) has taken on many forms. The final design of the system is composed of two vehicles, a lunar transfer vehicle (LTV) and a lunar excursion vehicle (LEV). The LTV serves as an efficient orbital transfer vehicle between the earth and the moon while the LEV carries crew and cargo to the lunar surface. Presented in the report are the mission analysis, systems layout, orbital mechanics, propulsion systems, structural and thermal analysis, and crew systems, avionics, and power systems for this lunar transportation concept. DESIGN OF A WHEELED ARTICULATING LAND ROVER
Larry Stauffer, Mathew Dilorenzo, and Barbara Yandle [1994] 103 p
(Contract NASw-4435)
(NASA-CR-195520; NAS 1.26:195520) Avail: CASI HC A06/MF A02

The WALRUS is a wheeled articulating land rover that will provide Ames Research Center with a reliable, autonomous vehicle for demonstrating and evaluating advanced technologies. The vehicle is one component of the Ames Research Center's on-going Human Exploration Demonstration Project. Ames Research Center requested a system capable of traversing a broad spectrum of surface types and obstacles. In addition, this vehicle must have an autonomous navigation and control system on board and its own source of power. The resulting design is a rover that articulates in two planes of motion to allow for increased mobility and stability. The rover is driven by six conical shaped aluminum wheels, each with an independent, internally coupled motor. Mounted on the rover are two housings and a removable remote control system. In the housings, the motor controller board, tilt sensor, navigation circuitry, and QED board are mounted. Finally, the rover's motors and electronics are powered by thirty C-cell rechargeable batteries, which are located in the rover wheels and recharged by a specially designed battery charger. Author

DESIGN AND APPLICATION OF ELECTROMECHANICAL ACTUATORS FOR DEEP SPACE MISSIONS Semiannual Progress Report No. 2, 16 Aug. 1993 - 15 Feb. 1994
Tim A. Haskew and John Wander Feb. 1994 72 p

(Grant NAG8-240)
(NASA-CR-195134; NAS 1.26:195134; BER-605-163) Avail: CASI HC A04/MF A01

This progress report documents research and development efforts performed from August 16, 1993 through February 15, 1994 on NASA Grant NAG8-240, 'Design and Application of Electromechanical Actuators for Deep Space Missions.' Following the executive summary are four report sections: Motor Selection, Tests Stand Development, Health Monitoring and Fault Management, and Experiment Planning. Three specific motor types have been considered as prime movers for TVC EMA applications: the brushless dc motor, the permanent magnet synchronous motor, and the induction motor. The fundamental finding was that, in general, the primary performance issues were energy efficiency and thermal dissipation (rotor heating). In terms of all other issues, the three motor types were found to compare quite equally. Among the design changes made to the test stand since the last progress report is the addition of more mounting holes in the side beams. These additional holes allow the movable end beam to be attached in a greater number of positions than previously. With this change the movable end beam can move from full forward to full back in three inch increments. Specific mathematical details on the approach that have been employed for health monitoring and fault management (HMFM) have been reported previously. This approach is based on and adaptive Kalman filter strategy. In general, a bank of filters can be implemented for each primary fault type. Presently under consideration for the brushless dc machine are the following faults: armature winding open-circuits, armature winding short-circuits (phase-to-phase and phase-to-ground), bearing degradation, and rotor flux weakening. The mechanically oriented experiments include transient loading experiments, transverse loading experiment, friction experiment, motor performance experiment, and HMFM experiment. Derived from text

THE H(SUB INFINITY) OPTIMAL CONTROLLER DESIGN AND REDUCTION FOR THE INERTIAL HOLD MODE OF THE ATTITUDE CONTROL SYSTEM OF THE XTE SPACECRAFT

Zhong Ling Xu and Gui An Zhou 5 Feb. 1994 27 p
(Grant NAG5-2210)
(NASA-CR-195137; NAS 1.26:195137) Avail: CASI HC A03/MF A01

The Inertial Hold Mode (IHM) is one mode of the attitude control system of the X-ray Timing Explorer spacecraft that is disturbed by both parametric uncertainties and external torque disturbance. The IHM model is modified into a typical H-infinity mixed-sensitivity problem through choosing suitable weighting functions W(sub 1)(s) and W(sub 3)(s). The controller is designed by the H-infinity optimization technique with the transformation of shifting the imaginary axis. It can stabilize the plant with uncertainties from the natural frequencies of the flexible body. The gain margin and phase margin of the system are 24.03 db and 55.04 deg, respectively. The step response attenuates to zero within 150 seconds. These show that the controller satisfies the specified requirements. Since the order of the controller appears high, it is reduced to fourth order one. The results show that the stability and the performance of the system with the reduced controller are retained perfectly. Author (revised)

A FINITE-ELEMENT-BASED PERTURBATION MODEL FOR THE ROTORDYNAMIC ANALYSIS OF SHROUDED PUMP IMPELLERS: PART 1: MODEL DEVELOPMENT AND APPLICATIONS Final Report

Erian A. Baskharone Sep. 1993 174 p
(Contract NAS8-37821)
(NASA-CR-193916; NAS 1.26:193916) Avail: CASI HC A08/MF A02

This study concerns the rotor dynamic characteristics of fluid-encompassed rotors, with special emphasis on shrouded pump impellers. The core of the study is a versatile and categorically new finite-element-based perturbation model, which is based on a rigorous flow analysis and what we have generically termed the 'virtually' deformable finite-element approach. The model is first applied to the case of a smooth annular seal for verification purposes. The rotor excitation components, in this sample problem, give rise to a purely cylindrical, purely conical, and a simultaneous cylindrical/conical rotor whirl around the housing centerline. In all cases, the computed results are compared to existing experimental and analytical data involving the same seal geometry and operating conditions. Next, two labyrinth-seal configurations, which share the same tooth-to-tooth chamber geometry but differ in the total number of chambers, were investigated. The results, in this case, are compared to experimental measurements for both seal configurations. The focus is finally shifted to the shrouded-impeller problem, where the stability effects of the leakage flow in the shroud-to-housing secondary passage are investigated. To this end, the computational model is applied to a typical shrouded-impeller pump stage, fabricated and rotor dynamically tested by Sulzer Bros., and the results compared to those of a simplified 'bulk-flow' analysis and Sulzer Bros.' test data. In addition to assessing the computed rotor dynamic coefficients, the shrouded-impeller study also covers a controversial topic, namely that of the leakage-passage inlet swirl, which was previously cited as the origin of highly unconventional (resonance-like) trends of the fluid-exerted forces. In order to validate this claim, a 'microscopic' study of the fluid/shroud interaction mechanism is conducted, with the focus being on the structure of the perturbed flow field associated with the impeller whirl. The conclusions of this study were solidified by the outcome of a numerical-certainty exercise, where the grid dependency of the numerical results is objectively examined. The final phase of the shrouded-impeller investigation involves the validation of a built-in assumption, in all other perturbation models, whereby single-harmonic tangential distributions of all the flow thermophysical properties are imposed. The last phase of the investigation course is aimed at verifying the fine details of the perturbed flow field in light of recent set of detailed LDA measurements in a smooth annular seal. Grid dependency of the fluid-induced forces is also investigated, and specific recommendations are made. Author (revised)

A FINITE-ELEMENT-BASED PERTURBATION MODEL FOR THE ROTORDYNAMIC ANALYSIS OF SHROUDED PUMP IMPELLERS: PART 2: USER'S GUIDE

Erian A. Baskharone Sep. 1993 75 p
(Contract NAS8-37821)
(NASA-CR-193917; NAS 1.26:193917) Avail: CASI HC A04/MF A01

This report describes the computational steps involved in executing a finite-element-based perturbation model for computing the rotor dynamic coefficients of a shrouded pump impeller or a simple seal. These arise from the fluid/rotor interaction in the clearance gap. In addition to the sample cases, the computational procedure also applies to a separate category of problems referred to as the 'seal-like' category. The problem, in this case, concerns a shrouded impeller, with the exception that the secondary, or leakage, passage is totally isolated from the primary-flow passage. The difference between this and the pump problem is that the former is analytically of the simple 'seal-like' configuration, with two (inlet and exit) flow-permeable stations, while the latter constitutes a double-entry / double-discharge flow problem. In all cases, the problem is that of a rotor clearance gap. The problem here is that of a rotor excitation in the form of a cylindrical whirl around the housing centerline for a smooth annular seal. In its centered operation mode, the rotor is assumed to give rise to an axisymmetric flow field in the clearance gap. As a result, problems involving longitudinal or helical grooves, in the rotor or housing surfaces, go beyond the code capabilities. Discarding, for the moment, the pre- and post-processing phases, the bulk of the computational procedure consists of two main steps. The first is aimed at producing the axisymmetric 'zeroth-order' flow solution in the given flow domain. Detailed description of this problem, including the flow-governing equations, turbulence closure, boundary conditions, and the finite-element formulation, was covered by Baskharone and Hensel. The second main step is where the perturbation model is implemented, with the input being the centered-rotor 'zeroth-order' flow solution and a prescribed whirl frequency ratio (whirl frequency divided by the impeller speed). The computational domain, in the latter case, is treated as three dimensional, with the number of computational planes in the circumferential direction being specified a priori. The reader is reminded that the deformations in the finite elements are all infinitesimally small because the rotor eccentricity itself is a virtual displacement. This explains why we have generically termed the perturbation model the 'virtually' deformable finite-element category. The primary outcome of implementing the perturbation model is the tangential and radial components, F(sub theta)(sup *) and F(sub r)(sup *) of the fluid-exerted force on the rotor surface due to the whirling motion. Repetitive execution of the perturbation

model subprogram over a sufficient range of whirl frequency ratios, and subsequent interpolation of these fluid forces, using the least-square method, finally enable the user to compute the impeller rotor dynamic coefficients of the fluid/rotor interaction. These are the direct and cross-coupled stiffness, damping, and inertia effects of the fluid/rotor interaction.

PRECISION DRIVE AND SPEED REDUCTION DEVICE Patent
Kenneth W. Stark, inventor (to Navy) 3 Aug. 1993 7 p Filed 16 Jul. 1991
(AD-D016004; US-Patent-Appl-SN-730620; US-Patent-Class-310-83) Avail: US Patent and Trademark Office

A method and device for precisely driving a rotary object are described. The device includes a motor mounted in a housing and a reduction device comprising first and second harmonic drives, which connect the motor to the object to be driven via an output shaft. The output shaft is connected to the object to be driven via an adapter cup and a bellows which is stiff in torsion but which tolerates misalignments between the drive device and the object. All elements are designed to maximize stiffness and precision and to minimize backlash while maintaining maximum concentricity between the elements. DTIC

ELECTRO-RHEOLOGICAL CONTROL VALVE Patent
Vincent M. Iorio, inventor (to Navy) and Joseph H. Morris, inventor (to Navy) 7 Sep. 1993 5 p Filed 21 Sep. 1992
(AD-D015997; US-Patent-5,241,991; US-Patent-Appl-SN-947591; US-Patent-Class-137-807) Avail: US Patent and Trademark Office

An E-R hydraulic control valve that has two or more surfaces that can be moved relatively to one another to adjust a flow orifice size while maintaining a control voltage gradient across the E-R fluid and to seat one surface against the other to shut off fluid flow. Combining movable mechanical fluid flow elements with E-R fluid control allows initial tuning of the valve to a particular application by mechanical restriction of an orifice, and E-R operating control of the fluid. Seating the mechanical surfaces provides a fail-safe shut-down mode. DTIC

ADVANCED LAUNCH SYSTEM. ADVANCED DEVELOPMENT OXIDIZER TURBOPUMP PROGRAM Final Report
29 Oct. 1993 294 p
(Contract NAS8-37595)
(NASA-CR-193920; NAS 1.26:193920; FR-23115) Avail: CASI HC A13/MF A03

On May 19, 1989, Pratt & Whitney was awarded contract NAS8-37595 by the National Aeronautics and Space Administration, Marshall Space Flight Center, Huntsville Alabama for an Advanced Development Program (ADP) to design, develop and demonstrate a highly reliable low cost, liquid oxygen turbopump for the Advanced Launch System (ALS). The ALS had an overall goal of reducing the cost of placing payloads in orbit by an order of magnitude. This goal would require a substantial reduction in life cycle costs, with emphasis on recurring costs, compared to current launch vehicles. Engine studies supporting these efforts were made for the Space Transportation Main Engine (STME). The emphasis on low cost required design simplification of components and subsystems such that the ground maintenance and test operations was minimized. The results of the Oxygen Turbopump ADP technology effort would provide data to be used in the STME. Initially the STME baseline was a gas generator cycle engine with a vacuum thrust level of 580,000 lbf. This was later increased to 650,000 lbf and the oxygen turbopump design approach was changed to reflect the new thrust level. It was intended that this ADP program be conducted in two phases. Phase 1, a basic phase, would encompass the preliminary design effort, and Phase II, an optional contract phase to cover design, fabrication and test evaluation of an oxygen turbopump at a component test facility at the NASA John C. Stennis Space Center in Mississippi. The basic phase included preliminary design and analysis, evaluation of low cost concepts, and evaluation of fabrication techniques. The option phase included design of the pump and support hardware, analysis of the final configuration to ensure design integrity, fabrication of hardware to demonstrate low cost, DVS Testing of hardware to verify the design, assembly of the turbopump and full scale turbopump testing. In December 1990, the intent of this ADP to support the design and development was changed. The design effort for the oxygen turbopump became part of the STME Phase B contract. The status of the pump design funded through this ADP was presented at the Preliminary Design Review (PDR) at the MSFC on October 24, 1990. Advancements in the design of the pump were subsequently continued under the Phase B Contract. The emphasis of this ADP became the demonstration of individual technologies that would have the greatest potential for reducing the recurring cost and increasing reliability. In October of 1992, overall program funding was reduced and work on this ADP was terminated. Derived from text

A joint helicopter transmission research program between NASA Lewis Research Center and the U.S. Army Research Lab has existed since 1970. Research goals are to reduce weight and noise while increasing life, reliability, and safety. These research goals are achieved by the NASA/Army Mechanical Systems Technology Branch through both in-house research and cooperative research projects with university and industry partners. Some recent significant technical accomplishments produced by this cooperative research are reviewed. The following research projects are reviewed: oil-off survivability of tapered roller bearings, design and evaluation of high contact ratio gearing, finite element analysis of spiral bevel gears, computer numerical control grinding of spiral bevel gears, gear dynamics code validation, computer program for life and reliability of helicopter transmissions, planetary gear train efficiency study, and the Advanced Rotorcraft Transmission (ART) program. Research to provide the up to date knowledge and efficient tools to design better Externally Pressurized Gas (EPG) bearing systems, including the design of individual bearings, and to arrange all the bearings used in an optimal way is reported. Both circular and rectangular EPG pads with rigid bearing surfaces and rigid inlet restrictors were used. The following topics closely related to the applications in precision engineering are discussed: influences of gap shape on the bearing performance; effects of bearing body tilt on the bearing performance; influences of bearing surface imperfections on bearing performance; temperature drops in EPG bearings in quasistationary conditions; the optimal use of multiple bearings in a mechanical system; the use of EPG bearing damping characteristics in the design; and the effects of motion velocity. Carnegie Mellon University's Autonomous Planetary Exploration Program (APEX) is currently building the Daedalus robot; a system capable of performing extended autonomous planetary exploration missions. Extended autonomy is an important capability because the continued exploration of the Moon, Mars and other solid bodies within the solar system will probably be carried out by autonomous robotic systems. There are a number of reasons for this - the most important of which are the high cost of placing a man in space, the high risk associated with human exploration and communication delays that make teleoperation infeasible. The Daedalus robot represents an evolutionary approach to robot mechanism design and software system architecture. Daedalus incorporates key features from a number of predecessor systems. Using previously proven technologies, the Apex project endeavors to encompass all of the capabilities necessary for robust planetary exploration. The Ambler, a six-legged walking machine was developed by CMU for demonstration of technologies required for planetary exploration. In its five years of life, the Ambler project brought major breakthroughs in various areas of robotic technology. Significant progress was made in: mechanism and control, by introducing a novel gait pattern (circulating gait) and use of orthogonal legs; perception, by developing sophisticated algorithms for map building; and planning, by developing and implementing the Task Control Architecture to coordinate tasks and control complex system functions. The APEX project is the successor of the Ambler project. Author (revised)

GENETIC-BASED MOTION PLANNING FOR ARTICULATED ROBOTIC MANIPULATORS
Kwong K. Chan and Ali M. S. Zalzala May 1993 6 p
(Grant RSG/323)
(RR-476; ETN-94-95142) Avail: CASI HC A02/MF A01

A genetic based algorithm for the minimum time trajectory planning of articulated robotic manipulators is proposed. The planning procedure is performed in the configuration space and respects all physical constraints imposed on the manipulator design, including the limits on the torque values applied to the motor of each joint of the arm. The complete nonlinear dynamic robot model is incorporated in the formulation. The purpose of the algorithm is to tessellate joint space into a grid of possible motion nodes, where at each option node, given the position and velocity at the previous node, possible velocity values are constrained by the time optimality together with the dynamics of the arm. The algorithm is proven to be more efficient than conventional heuristic search technique with a reduction of the execution time. ESA

Florida International University successfully completed the proposed project entitled, 'Research Experience for Undergraduates in Robotics and Materials.' Nineteen students designed and manufactured a 'user-friendly' industrial robot with three functional axes and an IBM-PC-based C-based controller. The accuracy of the robot is 0.0005 inch when two axes are used. An operator can control the motions of the robot with a few hours of training by using the PC-based controller mouse. The controller also provides graphical simulation of the robot motions. DTIC

(Contract W-31-109-eng-38)
(DE93-040273; ANL/ET/CP-79670; CONF-9308167-1) Avail: Issuing Activity (Department of Energy (DOE))

The purpose is to extend the analysis of a single plate or substrate to the case of a multilayered medium. Due to the requiring of higher operating frequency, lower attenuation, and stronger piezoelectricity, layered structure becomes necessary. This technique is rapidly applied in the field of nondestructive evaluation and testing (NDE/T). Recently, a new feature of applying the piezoelectric effect for remote sensing, actuating, and vibration controlling came under study and development in aerospace and automative industries. DOE

ANALYSIS OF A PROPOSED COMPTON BACKSCATTER IMAGING TECHNIQUE
J. Hall and B. Jacoby Dec. 1992 14 p Presented at the International Symposium on Substance Identification Technologies, Innsbruck, Austria, 4-8 Oct. 1993
(Contract W-7405-eng-36)
(DE93-040537; UCRL-JC-113254; CONF-9310164-3) Avail: CASI HC A03/MF A01

Imaging techniques which require access to only one side of the object being viewed are potentially useful in situations where conventional projection radiography and tomography cannot be applied, such as looking for voids in a large container where access to the back of the object is inconvenient or even impossible. One-sided imaging techniques are currently being used in nondestructive evaluation of surfaces and shallow subsurface structures. In this work we present both analytical calculations and detailed Monte Carlo simulations aimed at assessing the capability of a proposed Compton backscatter imaging technique designed to detect and characterize voids located several centimeters below the surface of a solid. The proposed technique, based on a scheme suggested by Farmer and Collins, encodes the spatial position and structure of voids in a solid in the energy spectrum of the Compton-scattered photons as recorded by a high resolution detector. Our calculations model a Cs-137 source projecting a 1 sq mm pencil beam of 662 keV gammas into a target slab at an incident angle of 45 degrees and a collimated detector (also oriented at 45 degrees with respect to the surface) which views the beam path at a central angle of 90 degrees. The detector collimator is modeled here as a triangular slit viewing a 2.54 cm (1.000 inch) segment of the beam path at a depth of 2 cm below the surface of the slab. Our results suggest that the proposed technique should be capable of an absolute position resolution of approximately 0.25 mm (approximately equal to 0.010 inches) for isolated voids and an overall object resolution of approximately 1 lp/mm (approximately 0.040 inches). The predicted signal contrast for voids packed with various contraband materials will be discussed as well as multiple scattering contributions to the predicted yields. DOE

ENGINE MATERIALS CHARACTERIZATION AND DAMAGE MONITORING BY USING X RAY TECHNOLOGIES

George Y. Baaklini Washington Oct. 1993 103 p Original contains color illustrations
(RTOP 510-01-50)
(NASA-TP-3328; E-7549; NAS 1.60:3328) Avail: CASI HC A06/MF A02; 29 functional color pages

X ray attenuation measurement systems that are capable of characterizing density variations in monolithic ceramics and damage due to processing and/or mechanical testing in ceramic and intermetallic matrix composites are developed and applied. Noninvasive monitoring of damage accumulation and failure sequences in ceramic matrix composites is used during room-temperature tensile testing. This work resulted in the development of a point-scan digital radiography system and an in situ x ray material testing system. The former is used to characterize silicon carbide and silicon nitride specimens, and the latter is used to image the failure behavior of silicon-carbide-fiber-reinforced, reaction-bonded silicon nitride matrix composites. State-of-the-art x ray computed tomography is investigated to determine its capabilities and limitations in characterizing density variations of subscale engine components (e.g., a silicon carbide rotor, a silicon nitride blade, and a silicon-carbide-fiber-reinforced beta titanium matrix rod, rotor, and ring). Microfocus radiography, conventional radiography, scanning acoustic microscopy, and metallography are used to substantiate the x ray computed tomography findings. Point-scan digital radiography is a viable technique for characterizing density variations in monolithic ceramic specimens. But it is very limited and time consuming in characterizing ceramic matrix composites. Precise x ray attenuation measurements, reflecting minute density variations, are achieved by photon counting and by using microcollimators at the source and the detector. X ray computed tomography is found to be a unique x ray attenuation measurement technique capable of providing cross-sectional spatial density information in monolithic ceramics and metal matrix composites. X ray computed tomography is proven to accelerate generic composite component development. Radiographic evaluation before, during, and after loading shows the effect of preexisting volume flaws on the fracture behavior of composites. Results from one-, three-, five-, and eight-ply ceramic composite specimens show that x ray film radiography can monitor damage accumulation during tensile loading. Matrix cracking, fiber-matrix debonding, fiber bridging, and fiber pullout are imaged throughout the tensile loading of the specimens. In situ film radiography is found to be a practical technique for estimating interfacial shear strength between the silicon carbide fibers and the reaction-bonded silicon nitride matrix. It is concluded that pretest, in situ, and post-test x ray imaging can provide greater understanding of ceramic matrix composite mechanical behavior. Author (revised)

AN EVALUATION OF COMPTON SCATTER IMAGING USING COMSCAN

R. D. Finlayson, W. Ramsbottom, and W. R. Sturrock May 1993 44 p
(DREP-TM-93-38; CTN-94-60921) Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada

A number of test samples, representative of aircraft materials and structures, were evaluated using a commercial x-ray backscatter radiation device called COMSCAN, developed by Philips. COMSCAN produces 22 simultaneous radiographic slices of a test object with only one-sided access. The slices, stored in computer memory, can then be paged through one at a time for viewing. The system has been integrated with a six-axis gantry robot system. During the COMSCAN evaluation, a number of test samples of graphite/epoxy, honeycomb, aluminum, and other low atomic number materials found on today's aircraft were scanned to determine the detectability of a variety of manufactured discontinuities including water in honeycomb, disbonds, delaminations, and corrosion. COMSCAN's ability to image a volume of 100 mm by 50 mm by 10 mm depth was very useful and allowed image display and analysis in both two and three dimensions. The collected images clearly show COMSCAN is well suited for detection of voids and defects where loss of material has occurred, such as corrosion pitting. COMSCAN, however, cannot detect delaminations. Author (CISTI)

SYSTEM FOR ANOMALY AND FAILURE DETECTION (SAFD) SYSTEM DEVELOPMENT Final Report

D. OReilly 30 Sep. 1993 220 p
(Contract NAS8-40000)
(NASA-CR-193907; NAS 1.26:193907) Avail: CASI HC A10/MF A03

The System for Anomaly and Failure Detection (SAFD) algorithm was developed as an improvement over the current redline system used in the Space Shuttle Main Engine Controller (SSMEC). Simulation tests and execution against previous hot fire tests demonstrated that the SAFD algorithm can detect engine failures as much as tens of seconds before the redline system recognized the failure. Although the current algorithm only operates during steady state conditions (engine not throttling), work is underway to expand the algorithm to work during transient conditions. This task assignment originally specified developing a platform for executing the algorithm during hot fire tests at Technology Test Bed (TTB) and installing the SAFD algorithm on that platform. Two units were built and installed in the Hardware Simulation Lab and at the TTB in December 1991. Since that time, the task primarily entailed improvement and maintenance of the systems, additional testing to prove the feasibility of the algorithm, and support of hot fire testing. This document addresses the work done since the last report of June 1992. The work on the System for Anomaly and Failure Detection during this period included improving the platform and the algorithm, testing the algorithm against previous test data and in the Hardware Simulation Lab, installing other algorithms on the system, providing support for operations at the Technology Test Bed, and providing routine maintenance. AN ANALYSIS OF TRADITIONAL OPERATIONAL TESTING TO PROJECT HOW TESTING WILL BE CONDUCTED IN THE FUTURE M.S. Thesis

Lawrence L. Turner, Jr. Sep. 1993 140 p
(AD-A273189) Avail: CASI HC A07/MF A02

The purpose is to analyze current operational testing and to alert the reader to how testing will be conducted in the future. This analysis is conducted from a tester's point of view and is targeted at program offices so that Program Managers will be able to ensure that beneficial operational testing is conducted on their programs. A detailed description of current and future systems used to instrument development systems, analyze the test data, and produce a final test report is provided. It also provides a detailed analysis of a testing tool called Model-Test-Model (M-T-M). The goal of M-T-M is to save the Army time and money by using a validated model to provide operational test data. Finally, an analysis of the changes that will need to be made in the T&E community as a result of a new defense environment is provided. These areas include the need for minimizing duplication between development and operational testing, using modeling and simulation, and taking advantage of other areas where testing costs can be reduced. NONDESTRUCTIVE EVALUATIONS
S. Kulkarni Mar. 1993 26 p
(Contract W-7405-eng-48)
(DE94-003020; UCRL-ID-112777) Avail: CASI HC A03/MF A01

This report discusses Nondestructive Evaluation (NDE) thrust area which supports initiatives that advance inspection science and technology. The goal of the NDE thrust area is to provide cutting-edge technologies that have promise of inspection tools three to five years in the future. In selecting projects, the thrust area anticipates the needs of existing and future Lawrence Livermore National Laboratory (LLNL) programs. NDE provides materials characterization inspections, finished parts, and complex objects to find flaws and fabrication defects and to determine their physical and chemical characteristics. NDE also encompasses process monitoring and control sensors and the monitoring of in-service damage. For concurrent engineering, NDE becomes a frontline technology and strongly impacts issues of certification and of life prediction and extension. In FY-92, in addition to supporting LLNL programs and the activities of nuclear weapons contractors, NDE has initiated several projects with government agencies and private industries to study aging infrastructures and to advance manufacturing processes. Examples of these projects are (1) the Aging Airplanes Inspection Program for the Federal Aviation Administration, (2) Signal Processing of Acoustic Signatures of Heart Valves for Shiley, Inc., and (3) Turbine Blade Inspection for the Air Force, jointly with Southwest Research Institute and Garrett. In FY-92, the primary contributions of the NDE thrust area, described in this report, were in fieldable chemical sensor systems, computed tomography, and laser generation and detection of ultrasonic energy. INVESTIGATION OF THE EFFECTS OF MANUFACTURING VARIATIONS AND MATERIALS ON FATIGUE CRACK DETECTION METHODS IN GEAR TEETH
Jeffrey A. Wheitner and Donald R. Houser Jan. 1994 114 p
(Grant NAG3-1147)
(NASA-CR-195093; NAS 1.26:195093) Avail: CASI HC A06/MF A02

The fatigue life of a gear tooth can be thought of as the sum of the number of cycles required to initiate a crack, N(sub i), plus the number of cycles required to propagate the crack to such a length that fracture occurs, N(sub p). The factors that govern crack initiation are thought to be related to localized stress or strain at a point, while propagation of a fatigue crack is a function of the crack tip parameters such as crack shape, stress state, and stress intensity factor. During a test there is no clear transition between initiation and propagation. The mechanisms of initiation and propagation are quite different and modeling them separately produces a higher degree of accuracy, but then the question that continually arises is 'what is a crack?' The total life prediction in a fracture mechanics model presently hinges on the assumption of an initial crack length, and this length can significantly affect the total life prediction. The size of the initial crack is generally taken to be in the range of 0.01 in. to 0.2 in. Several researchers have used various techniques to determine the beginning of the crack propagation stage. Barhorst showed the relationship between dynamic stiffness changes and crack propagation. Acoustic emissions, which are stress waves produced by the sudden movement of stressed materials, have also been successfully used to monitor the growth of cracks in tensile and fatigue specimens. The purpose of this research is to determine whether acoustic emissions can be used to define the beginning of crack propagation in a gear using a single-tooth bending fatigue test.

DEMONSTRATION OF POLYSCANN ULTRASONIC BUTT-FUSION INSPECTION SYSTEM FOR POLYETHYLENE PIPES Final Report
Orange S. Marshall, Jr. and James B. Hunt Jul. 1993 56 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273279; CERL-FEAP-TR-FM-93/06) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The demonstration of the Polyscann Ultrasonic Butt-Fusion Inspection System and laboratory research into its effectiveness as a quality control tool for installation of polyethylene pipe are described. In the demonstration, conducted at North Fort Hood, TX, 13 sections of 8 in. diameter polyethylene pipe were assembled and tied into a previously installed 8 in. gas pipeline. The system was successfully used to inspect each new butt-fusion joint in its entirety, and provided a computerized record of joint cross-sections and status. Laboratory tests indicated that the equipment results were mostly reliable, but it could not detect a low-density weld contaminant such as dried grass. Benefits of the Polyscann system include its nondestructive evaluation technology, capability of evaluating all joints without interrupting pipeline productivity, data-logging capabilities, ease of use, and ability to identify necessary repairs before the pipe is buried. After this demonstration was concluded, the manufacturer discontinued the system that was tested, and is redesigning it to be portable by one person and capable of detecting low-density contaminants such as grass. Price and release date for the updated system are pending. DTIC

RELIABILITY ANALYSIS OF A REPAIRABLE DEPENDENT PARALLEL SYSTEM Ph.D. Thesis
Marcus Johannes Petr Pijnenburg 1992 211 p
(ETN-94-95312) Avail: CASI HC A10/MF A03

A study to develop a stochastic model to describe a system's failure behavior is reported. The systems analyzed are thought of as industrial machinery, equipment, or products. Basic stochastic models in reliability theory are introduced. Systems with bivariate exponentially distributed life times, phase type distributed life and repair times, and bivariate phase type distributed life times are studied. An opportunistic replacement policy for the two unit dependent parallel system, in continuous time and at component level, is described. The gradual deterioration of the parallel system is considered. ESA

FAULT DETECTION IN HVAC SYSTEMS USING FUZZY MODELS
A. L. Dexter and B. K. K. Mok 1993 28 p
(OUEL-1977/93; AN25/UK/151092/1.1; ETN-94-95160) Avail: CASI HC A03/MF A01

A fault detection scheme which uses qualitative models, consisting of sets of fuzzy rules, to describe the generic behavior of both fault free and faulty operation of plant is described. It is applied to Heating, Ventilating and Air Conditioning (HVAC) systems. These fuzzy reference models are generated off line from training data produced by computer simulation of a typical plant, with and without the faults, using a fuzzy identification scheme. A computationally efficient, fuzzy identification algorithm, that is suitable for implementation in packaged controls, is used to estimate the credibility of each of the rules. Faults are detected by comparing the behavior of the plant with the behavior predicted by the fuzzy reference models. Two methods of comparing the actual and predicted behavior are examined: a prediction based method in which faults are detected by comparing measurements, available from the building energy management system connected to the plant, with the predictions of the fuzzy reference models; and a rule similarity method in which data collected on line from the real plant are used to identify a partial fuzzy model. The degree to which faulty or correct operation is present, is determined by comparing the rules of the partial fuzzy model with the rules of the fuzzy reference models, using a fuzzy measure of similarity. Results which demonstrate the ability of both schemes to detect faults in the mixing box of the air handling unit of an air conditioning system are presented. ESA

FRACTURE SIMULATIONS VIA MASSIVELY PARALLEL MOLECULAR DYNAMICS
B. L. Holian, F. F. Abraham (International Business Machines Corp., San Jose, CA.), and R. Ravelo (Texas Univ., El Paso.) 1993 11 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993
(Contract W-7405-eng-36)
(DE93-040159; LA-UR-93-3184; CONF-931121-22) Avail: CASI HC A03/MF A01

Fracture simulations at the atomistic level have been carried out for relatively small systems of particles, typically 10,000 or less. In order to study anything approaching a macroscopic system, massively parallel molecular dynamics (MD) must be employed. In two spatial dimensions (2D), it is feasible to simulate a sample that is 0.1 microns on a side. Recent MD simulations of mode 1 crack extension under tensile loading at high strain rates are reported. The method of uniaxial, homogeneously expanding periodic boundary conditions was employed to represent tensile stress conditions near the crack tip. The effects of strain rate, temperature, material properties (equation of state and defect energies), and system size were examined. It was found that, in order to mimic a bulk sample, several tricks (in addition to expansion boundary conditions) need to be employed: (1) the sample must be pre-strained to nearly the condition at which the crack will spontaneously open; (2) to relieve the stresses at free surfaces, such as the initial notch, annealing by kinetic-energy quenching must be carried out to prevent unwanted rarefactions; (3) sound waves emitted as the crack tip opens and dislocations emitted from the crack tip during blunting must be absorbed by special reservoir regions. The tricks described briefly will be especially important to carrying out feasible massively parallel 3D simulations via MD. DOE

PROOF TEST OF THE COMPUTER PROGRAM BUCKY FOR PLASTICITY PROBLEMS
James P. Smith Jan. 1994 10 p
(NASA-TP-3444; S-753; NAS 1.60:3444) Avail: CASI HC A02/MF A01

A theoretical equation describing the elastic-plastic deformation of a cantilever beam subject to a constant pressure is developed. The theoretical result is compared numerically to the computer program BUCKY for the case of an elastic-perfectly plastic specimen. It is shown that the theoretical and numerical results compare favorably in the plastic range. Comparisons are made to another research code to further validate the BUCKY results. This paper serves as a quality test for the computer program BUCKY developed at NASA Johnson Space Center. Author

CONTROL OF THE INTERNAL STRESSES IN PLANE ELASTICITY
S. Bennati (Pisa Univ., Italy.), S. DegIInnocenti, and C. Padovani 1993 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-225514) Avail: Issuing Activity (National Technical Information Service (NTIS))

A circular domain is subjected to radial surface forces varying according to a sinusoidal law. The existence of a tensile region included in a purely compressive one is proven and its asymptotic behavior studied when the surface forces converge to two concentrated loads acting along a same diameter. The results show that any maximum principle for the principal stress components would require conditions stronger than the simple negativity of both on the boundary of the domain. NTIS

DEVELOPMENT OF SMALL PUNCH TESTING TECHNIQUE AND ITS APPLICATION TO EVALUATION OF MECHANICAL PROPERTIES DEGRADATION
J. Kameda 1993 18 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-7405-eng-82)
(DE94-001193; IS-M-772; CONF-931009-5) Avail: CASI HC A03/MF A01

The present paper summarizes a small punch (SP) testing technique developed and its application to mechanical properties characterization. It has been clearly shown on ferritic alloys that the SP test was evaluate the intergranular embrittling potency of segregated solute, such as P, Sn and Sb causing temper embrittlement, and the effects of neutron irradiation and post-irradiation annealing, giving rise to changes in the hardness and intergranular solute segregation, on the fracture properties in terms of the ductile-brittle transition temperature (DBTT). A linear relation of the DBTT determined by the SP test to that by Charpy V-notched tests has been theoretically and experimentally established. In Al alloy substrates coated with amorphous and overlaying ceramics, moreover, the global and local fracture properties were well characterized by the SP test together with acoustic emission techniques. (Contract DE-AC04-94AL-85000)
(DE94-001706; SAND-93-1287) Avail: CASI HC A06/MF A02

Cellular materials consist of interconnected struts or plates which form cells. The struts or plates are constructed from a variety of metals, polymers, ceramics, and wood products. Cellular materials are often used in impact limiters for shipping containers to protect the contents from accidental impact events. These materials exhibit a variety of complex behavior when subjected to crushing loads. This research focuses on the development of continuum representations of cellular solids that can be used in the finite element analysis of shipping container accidents. A significant portion of this work is the development of a new methodology to relate localized deformations to appropriate constitutive descriptions. This methodology provides the insight needed to select constitutive descriptions for cellular solids that capture the localized deformations that are observed experimentally. Constitutive relations are developed for two different cellular materials, aluminum honeycomb and polyurethane foam. These constitutive relations are based on plasticity and continuum damage theories. Plasticity is used to describe the permanent deformation exhibited by both aluminum honeycomb and polyurethane foam. Continuum damage is needed to capture the change in elastic parameters due to cracking of the polyurethane cell wall materials. The new constitutive description of polyurethane foam is implemented in both static and dynamic finite element codes, and analytical and numerical predictions are compared with available experimental data. ANALYSIS AND TEST OF LOW PROFILE ALUMINUM AEROSPACE TANK DOME
R. Ahmed and J. M. Wilhelm Washington Dec. 1993 37 p
(NASA-TP-3442; M-737; NAS 1.60:3442) Avail: CASI HC A03/MF A01

In order to increase the structural performance of cryogenic tanks, the aerospace industry is beginning to employ low-profile bulkheads in new generation launch vehicle designs. This report details the analysis and test of one such dome made from 2219 aluminum. Such domes have two potential failure modes under internal pressure, general tensile failure and hoop compression buckling (in regions near the equator). The test determined the buckling load and ultimate tensile load of the hardware and showed that both compared well with the analysis predictions. This effort was conducted under the auspices of NASA and the General Dynamics Cryogenic Tank Technology Program (CTTP). Author (revised)

REVIEW OF THE PROBABILISTIC FAILURE ANALYSIS METHODOLOGY AND OTHER PROBABILISTIC APPROACHES FOR APPLICATION IN AEROSPACE STRUCTURAL DESIGN

J. Townsend, C. Meyers, R. Ortega, J. Peck, M. Rheinfurth, and B. Weinstock (Vitro Corp., Washington, DC.) Washington Nov. 1993 72 p
(NASA-TP-3434; M-734; NAS 1.60:3434) Avail: CASI HC A04/MF A01

Probabilistic structural analyses and design methods are steadily gaining acceptance within the aerospace industry. The safety factor approach to design has long been the industry standard, and it is believed by many to be overly conservative and thus, costly. A probabilistic approach to design may offer substantial cost savings. This report summarizes several probabilistic approaches: the probabilistic failure analysis (PFA) methodology developed by Jet Propulsion Laboratory, fast probability integration (FPI) methods, the NESSUS finite element code, and response surface methods. Example problems are provided to help identify the advantages and disadvantages of each method. Author (revised)

A STRUCTURAL DESIGN DECOMPOSITION METHOD UTILIZING SUBSTRUCTURING

Stephen J. Scotti Jan. 1994 16 p
(RTOP 505-63-50-08)
(NASA-TM-107750; NAS 1.15:107750) Avail: CASI HC A03/MF A01

A new method of design decomposition for structural analysis and optimization is described. For this method, the structure is divided into substructures where each substructure has its structural response described by a structural-response subproblem, and its structural sizing determined from a structural-sizing subproblem. The structural responses of substructures that have rigid body modes when separated from the remainder of the structure are further decomposed into displacements that have no rigid body components, and a set of rigid body modes. The structural-response subproblems are linked together through forces determined within a structural-sizing coordination subproblem which also determines the magnitude of any rigid body displacements. Structural-sizing subproblems having constraints local to the substructures are linked together through penalty terms that are determined by a structural-sizing coordination subproblem. All the substructure structural-response subproblems are totally decoupled from each other, as are all the substructure structural-sizing subproblems, thus there is significant potential for use of parallel solution methods for these subproblems. STRAIN GAGE MEASUREMENT ERRORS IN THE TRANSIENT HEATING OF STRUCTURAL COMPONENTS

W. Lance Richards Washington Dec. 1993 15 p Presented at the SEM Fall Connference and Exhibit: Structural Testing at High Temperature 2, Ojai, CA, 8-10 Nov. 1993
(RTOP 505-70-63)
(NASA-TM-104274; H-1960; NAS 1.15:104274) Avail: CASI HC A03/MF A01

Significant strain-gage errors may exist in measurements acquired in transient thermal environments if conventional correction methods are applied. Conventional correction theory was modified and a new experimental method was developed to correct indicated strain data for errors created in radiant heating environments ranging from 0.6 C/sec (1 F/sec) to over 56 C/sec (100 F/sec). In some cases the new and conventional methods differed by as much as 30 percent. Experimental and analytical results were compared to demonstrate the new technique. For heating conditions greater than 6 C/sec (10 F/sec), the indicated strain data corrected with the developed technique compared much better to analysis than the same data corrected with the conventional technique. MATERIAL DATA REPRESENTATION OF HYSTERESIS LOOPS FOR HASTELLOY X USING ARTIFICIAL NEURAL NETWORKS

Javed Alam (Youngstown State Univ., OH.), Laszlo Berke, and Pappu L. N. Murthy Dec. 1993 11 p
(RTOP 505-63-5B)
(NASA-TM-105990; E-7301; NAS 1.15:105990) Avail: CASI HC A03/MF A01

The artificial neural network (ANN) model proposed by Rumelhart, Hinton, and Williams is applied to develop a functional approximation of material data in the form of hysteresis loops from a nickel-base superalloy, Hastelloy X. Several different ANN configurations are used to model hysteresis loops at different cycles for this alloy. The ANN models were successful in reproducing the hysteresis loops used for its training. However, because of sharp bends at the two ends of hysteresis loops, a drift occurs at the corners of the loops where loading changes to unloading and vice versa (the sharp bends occurred when the stress-strain curves were reproduced by adding stress increments to the preceding values of the stresses). Therefore, it is possible only to reproduce half of the loading path. The generalization capability of the network was tested by using additional data for two other hysteresis loops at different cycles. The results were in good agreement. Also, the use of ANN led to a data compression ratio of approximately 22:1. Author

A STRUCTURAL DESIGN METHODOLOGY FOR LARGE ANGLE ARTICULATED TRUSSES CONSIDERING REALISTIC JOINT MODELING

Gregory Thorwald and Martin M. Mikulas, Jr. 31 Jan. 1994 226 p
Avail: CASI HC A11/MF A03

A structural design methodology is developed by quantifying the magnitude that large angle articulations and realistic modeling considerations adversely affect a truss's structural stiffness. Batten actuators provide the ability for the truss both to deploy and articulate. Such an articulated truss can be used in space crane applications. With geometry and modeling considerations identified and examined, strategies to alleviate the truss's stiffness reduction are developed and evaluated. Using these strategies, an improved articulated truss is then demonstrated. Observing that the design strategies are effective for the planar truss models similar 3-D truss models are then analyzed. The results show that the improvement strategies benefit both the 2-D and 3-D truss models. Author

MODELING DYNAMICALLY COUPLED FLUID-DUCT SYSTEMS WITH FINITE LINE ELEMENTS Final Report

J. B. Saxon Feb. 1994 17 p
(Contract NAS8-38550)
(NASA-CR-193909; NAS 1.26:193909) Avail: CASI HC A03/MF A01

Structural analysis of piping systems, especially dynamic analysis, typically considers the duct structure and the contained fluid column separately. Coupling of these two systems, however, forms a new dynamic system with characteristics not necessarily described by the superposition of the two component system's characteristics. Methods for modeling the two coupled components simultaneously using finite line elements are presented. Techniques for general duct intersections, area or direction changes, long radius bends, hydraulic losses, and hydraulic impedances are discussed. An example problem and results involving time transients are presented. Additionally, a program to enhance post-processing of line element models is discussed. Author

HYDRO-ELASTIC ANALYSIS USING A SELECTION OF COMMERCIAL ANALYSIS PROGRAMS Final Report No. 2

1993 70 p Sponsored by Stichting Coordinatie Maritiem Onderzoek, Rotterdam, The Netherlands

(PB94-118734; TNO-93-CMC-R0210-2) Copyright Avail: CASI HC A04/MF A01

It has been investigated whether and how a number of commercial finite element software systems can be used for predicting the response of a ship hull to excitation by a cavitating propeller. In this typical fluid-structure interaction problem, the cavitating propeller is represented as a monopole source. The software systems considered in this study are DIANA, MSC/NASTRAN, SYSNOISE, ABAQUS, and USA-CODE. For calculating the response for the frequency range of interest, it is sufficient to model the surrounding water by an incompressible fluid without free surface waves and radiation damping. It is shown how to model a monopole in a finite element response analysis if the system does not allow for a direct input of a monopole. It is found that software which uses boundary elements for describing the fluid domain is strongly preferable in this type of analysis. This saves the laborious work required for 3D meshing of the fluid domain and hence makes 3D response analyses of ship hulls feasible. For a two dimensional test case, results obtained with different software systems showed large deviations compared to each other and to an analytical solution. NTIS

DAMAGE TOLERANCE OF PRESSURIZED GRAPHITE/EPOXY TAPE CYLINDERS UNDER UNIAXIAL AND BIAXIAL LOADING M.S. Thesis

Stacy Marie Priest Dec. 1993 318 p

(Grant NAG1-991)

(NASA-CR-195101; NAS 1.26:195101; TELAC-93-19) Avail: CASI HC A14/MF A03

The damage tolerance behavior of internally pressurized, axially slit, graphite/epoxy tape cylinders was investigated. Specifically, the effects of axial stress, structural anisotropy, and subcritical damage were considered. In addition, the limitations of a methodology which uses coupon fracture data to predict cylinder failure were explored. This predictive methodology was previously shown to be valid for quasi-isotropic fabric and tape cylinders but invalid for structurally anisotropic (+/-45/90)(sub s) and (+/-45/0)(sub s) cylinders. The effects of axial stress and structural anisotropy were assessed by testing tape cylinders with (90/0/+/-45)(sub s), (+/-45/90)(sub s), and (+/-45/0)(sub s) layups in a uniaxial test apparatus, specially designed and built for this work, and comparing the results to previous tests conducted in biaxial loading. Structural anisotropy effects were also investigated by testing cylinders with the quasi-isotropic (0/+/-45/90)(sub s) layup which is a stacking sequence variation of the previously tested (90/0/+/-45)(sub s) layup with higher D(sub 16) and D(sub 26) terms but comparable D(sub 16) and D(sub 26) to D(sub 11) ratios. All cylinders tested and used for comparison are made from AS4/3501-6 graphite/epoxy tape and have a diameter of 305 mm. Cylinder slit lengths range from 12.7 to 50.8 mm. Failure pressures are lower for the uniaxially loaded cylinders in all cases. The smallest percent failure pressure decreases are observed for the (+/-45/90)(sub s) cylinders, while the greatest such decreases are observed for the (+/-45/0)(sub s) cylinders. The relative effects of the axial stress on the cylinder failure pressures do not correlate with the degree of structural coupling. The predictive methodology is not applicable for uniaxially loaded (+/-45/90)(sub s) and (+/-45/0)(sub s) cylinders, may be applicable for uniaxially loaded (90/0/+/-45)(sub s) cylinders, and is applicable for the biaxially loaded (90/0/+/-45)(sub s) and (0/+/-45/90)(sub s) cylinders. This indicates that the ratios of D(sub 16) and D(sub 26) to D(sub 11), as opposed to the absolute magnitudes of D(sub 16) and D(sub 26), may be important in the failure of these cylinders and in the applicability of the methodology. Discontinuities observed in the slit tip hoop strains for all the cylinders tested indicate that subcritical damage can play an important role in the failure of tape cylinders. This role varies with layup and loading condition and is likely coupled to the effects of structural anisotropy. Biaxial failure pressures may exceed the uniaxial values because the axial stress contributes to the formation of 0 deg ply splitting (accompanied by delamination) or similar stress-mitigating subcritical damage. The failure behavior of similar cylinders can also vary as a result of differences in the role of subcritical damage as observed for the case of a biaxially loaded (90/0/+/-45)(sub s) cylinder with a 12.7 mm slit. For this case, the methodology is valid when the initial coupon and cylinder fracture modes agree. However, the methodology underpredicts the failure pressure of the cylinder when a circumferential fracture path, suggestive of a 0 deg ply split, occurs at one slit tip. Thus, the failure behavior of some tape cylinders may be highly sensitive to the initial subcritical damage mechanism. Finite element analyses are recommended to determine how structural anisotropy and axial stress modify the slit tip stress states in cylinders from those found in flat plates since similarity of these stress states is a fundamental assumption of the current predictive methodology. THE EFFECTS OF ANISOTROPY ON THE NONLINEAR BEHAVIOR OF BRIDGED CRACKS IN LONG STRIPS Final Report

R. Ballarini and H. A. Luo (Xian Jiaotong Univ., China.) Feb. 1994 39 p

(Grant NAG3-856; RTOP 505-63-5B)

(NASA-CR-194453; E-8388; NAS 1.26:194453) Avail: CASI HC A03/MF A01

A model which can be used to predict the two-dimensional nonlinear behavior of bridged cracks in orthotropic strips is presented. The results obtained using a singular integral equation formulation which incorporates the anisotropy rigorously show that, although the effects of anisotropy are significant, the nondimensional quantities employed by Cox and Marshall can generate nearly universal results (R-curves, for example) for different levels of relative anisotropy. The role of composite constituent properties in the behavior of bridged cracks is clarified. Author (revised)

STABILITY ANALYSIS OF ANISOTROPIC CONICAL SHELLS Ph.D. Thesis

Guo-Qi Zhang 1993 295 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-119054; ISBN-90-6275-876-2/CIP) Copyright Avail: CASI HC A13

In this investigation, a rigorous treatment of the bifurcation buckling and initial postbuckling behavior of perfect and imperfect anisotropic conical shells is presented, which includes the effects of boundary conditions and nonlinear prebuckling deformations. This analysis is based on nonlinear Donnell-type strain-displacement relations and uses an extension of Koiter's initial postbuckling theory. To carry out the above analysis, the nonlinear Donnell-type anisotropic shell equations in terms of the radial displacement W and the Airy stress function F are derived via the stationary potential energy criterion. A complete set of boundary conditions, which partially or completely satisfies Seide's geometric constraint, is also formulated in terms of W and F. By using the perturbation technique proposed by Koiter, three sets of differential equations governing the prebuckling, buckling, and postbuckling problems, and the corresponding boundary conditions are obtained. To solve the resulting boundary value problems, the nonlinear prebuckling solution is assumed to be axisymmetric, while the circumferential dependence of the buckling and postbuckling equations is eliminated by Fourier decomposition. ELEVATED TEMPERATURE CRACK PROPAGATION

Thomas W. Orange Feb. 1994 17 p Presented at the Symposium on Fatigue and Fracture, 114th Winter Annual Meeting, New Orleans, LA, 29 Nov. - 3 Dec. 1993; sponsored by ASME

(RTOP 505-63-5B)

(NASA-TM-106490; E-8477; NAS 1.15:106490) Avail: CASI HC A03/MF A01

This paper is a summary of two NASA contracts on high temperature fatigue crack propagation in metals. The first evaluated the ability of fairly simple nonlinear fracture parameters to correlate crack propagation. Hastelloy-X specimens were tested under isothermal and thermomechanical cycling at temperatures up to 980 degrees C (1800 degrees F). The most successful correlating parameter was the crack tip opening displacement derived from the J-integral. The second evaluated the ability of several path-independent integrals to correlate crack propagation behavior. Inconel 718 specimens were tested under isothermal, thermomechanical, temperature gradient, and creep conditions at temperatures up to 650 degrees C (1200 degrees F). The integrals formulated by Blackburn and by Kishimoto correlated the data reasonably well under all test conditions. Author (revised)

VARIABLE AMPLITUDE FATIGUE, MODELLING AND TESTING
T. Svensson 1993 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-204469; SP-RAPP-1993:13) Avail: CASI HC A04

Problems related to metal fatigue modelling and testing are here treated in four different papers. In the first paper different views of the subject are summarized in a literature survey. In the second paper a new model for fatigue life is investigated. Experimental results are established which are promising for further development of the model. In the third paper a method is presented that generates a stochastic process, suitable to fatigue testing. The process is designed in order to resemble certain fatigue related features in service life processes. In the fourth paper fatigue problems in transport vibrations are treated. NTIS

BUCKLING OF CIRCULAR CYLINDRICAL SHELLS SUBJECTED TO COMBINED LOADS (AXIAL COMPRESSION, NORMAL PRESSURE, BENDING AND TRANSVERSE SHEAR LOADING)
E. Karyadi Sep. 1992 19 p See also PB91-114637 and PB92-199611 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-215358; M-663) Avail: Issuing Activity (National Technical Information Service (NTIS))

The paper deals with the buckling behavior of anisotropic or isotropic stiffened cylindrical shells subjected to combined loading defined in the title. A rigorous satisfaction of the boundary conditions at the ends of the cylinder was included. The analysis is started with the formulation of the buckling equations for anisotropic stiffened cylinders under the specified loading condition. In this stage of analysis, membrane condition of prebuckling stresses in the cylinder is assumed. Further, to solve the buckling equations, solution functions in terms of the independent displacement variables u, v and w are introduced. In order to satisfy the homogeneous boundary conditions, the axial dependence of the displacement variables is assumed to be an unknown function of the axial coordinate. In the circumferential direction, Fourier series expansions will be applied. By using the Galerkin process and a finite difference approximation, the buckling equations will be reduced to a standard eigenvalue problem. For calculating the eigenvalues and the corresponding mode shapes, the requisite software is developed. NTIS

DYNAMIC ANALYSIS OF PRETWISTED ELASTICALLY-COUPLED ROTOR BLADES
Mark W. Nixon and Howard E. Hinnant Jan. 1994 19 p Presented at the 1992 ASME Winter Annual Meeting, Anaheim, CA, 8-13 Nov. 1992 See also A93-21125
(RTOP 505-63-50-15)
(NASA-TM-109070; NAS 1.15:109070) Avail: CASI HC A03/MF A01

The accuracy of using a one-dimensional analysis to predict frequencies of elastically-coupled highly-twisted rotor blades is addressed. Degrees of freedom associated with shear deformation are statically condensed from the formulation, so the analysis uses only those degrees of freedom associated with classical beam theory. The effects of cross section deformation (warping) are considered, and are shown to become significant for some types of elastic coupling. Improved results are demonstrated for highly-coupled blade structures through account of warping in a local cross section analysis, without explicit inclusion of these effects in the beam analysis. A convergence study is also provided which investigates the potential for improving efficiency of elastically-coupled beam analysis through implementation of a p-version beam finite element. MERITS AND LIMITATIONS OF OPTIMALITY CRITERIA METHOD FOR STRUCTURAL OPTIMIZATION
Surya N. Patnaik (Ohio Aerospace Inst., Brook Park.), James D. Guptill, and Laszlo Berke Washington Nov. 1993 49 p
(RTOP 505-63-1C)
(NASA-TP-3373; E-7325; NAS 1.60:3373) Avail: CASI HC A03/MF A01

The merits and limitations of the optimality criteria (OC) method for the minimum weight design of structures subjected to multiple load conditions under stress, displacement, and frequency constraints were investigated by examining several numerical examples. The examples were solved utilizing the Optimality Criteria Design Code that was developed for this purpose at NASA Lewis Research Center. This OC code incorporates OC methods available in the literature with generalizations for stress constraints, fully utilized design concepts, and hybrid methods that combine both techniques. Salient features of the code include multiple choices for Lagrange multiplier and design variable update methods, design strategies for several constraint types, variable linking, displacement and integrated force method analyzers, and analytical and numerical sensitivities. The performance of the OC method, on the basis of the examples solved, was found to be satisfactory for problems with few active constraints or with small numbers of design variables. For problems with large numbers of behavior constraints and design variables, the OC method appears to follow a subset of active constraints that can result in a heavier design. The computational efficiency of OC methods appears to be similar to some mathematical programming techniques. Author

PROBABILISTIC ASSESSMENT OF SMART COMPOSITE STRUCTURES
Christos C. Chamis and Michael C. Shiao (Sverdrup Technology, Inc., Brook Park, OH.) Jan. 1994 21 p Presented at the 38th International SAMPE Symposium and Exhibit, Anaheim, CA, 10-13 May 1993; sponsored by the Society for the Advancement of Materials and Process Engineering
(RTOP 510-02-12)
(NASA-TM-106358; E-8145; NAS 1.15:106358) Avail: CASI HC A03/MF A01

A composite wing with spars and bulkheads is used to demonstrate the effectiveness of probabilistic assessment of smart composite structures to control uncertainties in distortions and stresses. Results show that a smart composite wing can be controlled to minimize distortions and to have specified stress levels in the presence of defects. Structural responses such as changes in angle of attack, vertical displacements, and stress in the control and controlled plies are probabilistically assessed to quantify their respective uncertainties. Sensitivity factors are evaluated to identify those parameters that have the greatest influence on a specific structural response. Results show that smart composite structures can be configured to control both distortions and ply stresses to satisfy specified design requirements. Author

USE OF PHOTOSTRESS TO CHARACTERIZE THE MECHANICAL BEHAVIOR OF WELDMENTS Final Report
S. C. Gambrell, Jr. Sep. 1992 143 p Original contains color illustrations
(Grant NAG8-212)
(NASA-CR-195201; NAS 1.26:195201; BER-570-97) Avail: CASI HC A07/MF A02; 19 functional color pages

Welded aluminum is an important part of many space structures. Knowledge of the properties and behavior of weld material and the material surrounding the weld is important for modeling and design of the structures. Photoelastic coatings (Photostress) and strain gages were used to determine behavior of heat treated and as welded joints made from 2219T87 parent material and 2319 weld material subjected to tensile loads. TIG welds of

1/8, 1/2, and 1.4 inches thickness were investigated. Discontinuous yielding was observed in all tests and highly non-uniform behavior through the weld thickness was observed in joints having welds 1.4 inches thick. Joints having welds 1/8 and 1/2 inches thick had only small differences in behavior through the thickness of the weld. Joints in the 1/2 inch thick material contained distinct zones of constant strain within the normal strain gradient extending outward from the weld centerline. These zones had different thickness and locations. Points at the weld centerline, and for a distance of nearly one inch from the centerline, exhibited very nonlinear behavior during the first loading but exhibited near perfect strain hardening during the second loading. RING NUCLEI OF STRAIN FOR BONDED DISSIMILAR ELASTIC HALF SPACES WITH PARTICULAR APPLICATION TO AXISYMMETRIC CRACK PROBLEMS
Alexander M. Korsunsky 1992 29 p
(OUEL-1966/92; ETN-94-95152) Avail: CASI HC A03/MF A01

A class of fundamental solutions for axisymmetric elastic problems for two perfectly bonded dissimilar elastic half spaces is developed. The nuclei of strain corresponding to infinitesimal dislocation loops (finite displacement discontinuities prescribed over infinitesimal area) are chosen as the starting point. These are integrated along a circular contour to produce the solutions for normal axial, normal radial, and tangential displacement discontinuities along a ring. Formulae for stresses in the material containing the nuclei of strain are given in terms of the Lipschitz-Hankel type integrals, which in their turn are expressed using elliptic functions. ESA

The mechanics of fiber reinforced concrete under uniaxial loading is studied. The focus is on the behavior after cracking. The interaction between the fiber and the matrix is the shear stress transfer. The stress can be elastic or frictional in nature. The bond parameters can be obtained by a simple pull-out test and theory. The load displacement curves for fibers of different lengths can be created by means of the calculated parameters. In a simple constitutive model, the main assumption is that the fibers are continuous and there exists multiple cracking in the matrix. After cracking, the fibers only carry the loading. The model uses efficiency factors in taking into account the short and randomly distributed fibers. Only the strengthening portion of the stress strain curve is analyzed. In the statistical model created, it is assumed that only one crack will develop. The theory ignores the strain of the matrix in fiber pull-out. The strain softening behavior is taken into consideration. A constitutive model which takes into account the strain softening part of the stress strain curve is developed. The crack distance and crack width are also calculated. The model takes into account one crack or multiple cracking states and different fracture mechanisms: fiber fracture or pull-out. The fibers are smooth and straight. They can be short or continuous, aligned or randomly distributed, brittle or ductile, and stiff or flexible. Different types of fibers may lie in the same matrix. The results of the model are consistent with the other two models referred. The effects of different parameters can be studied and even new formulas can be found. The model can be used in the design of composite materials and is valid for other brittle matrix composites, such as fiber reinforced ceramics. ESA

Non-insulated GRFP (Glass Fiber Reinforced Plastics) pipes were experimentally investigated. Particular consideration was given to the effects of short term thermal overloads and impact damage. It was shown that for a matrix with a long term specified service temperature of less than 140 C and starting from 140 C at 10 bar pressure up to 200 C and 30 bar pressure up to 170 C such thermalcycling up to some 100 cycles is acceptable when the hold time at the peak temperature is less than one hour. A prerequisite for this is the outer surface of the pipes remaining non-insulated and cooler (by about 30 C) than the content. No significant creep strain under static 10 bar pressure at 140 C was measured up to 350 hours of testing time. At 200 C and 30 bar, creep was fast enough to produce failure in a few hours. Clearly, the matrix material is not well suited to these high temperatures. Nevertheless, temporary surges in inside temperature to 170 C or even relatively long periods peaking at 140 C should not cause significant problems at normal service pressures near 10 bar, at least up to some 100 cycles. Impact testing and subsequent static pressure testing showed that for a given type of material, the leakage pressure of the vessel can be relatively easily predicted from the incident impact energy or from the ultrasonically determined size of the impact defect. ESA

THE COMPLETE STRESS FIELD DUE TO A DISLOCATION LOCATED ANYWHERE IN TWO BONDED QUARTER PLANES
P. Kelly, D. A. Hills, and D. Nowell 1993 31 p
(OUEL-1990/93; ETN-94-95161) Avail: CASI HC A03/MF A01

A method to deal with the state of stress arising anywhere within the two quarter planes induced by a dislocation situated anywhere within the quarter planes is developed. It provides the means of solving the problem of a crack lying anywhere within the quarter planes. This problem is of some practical importance as the fracture resistance of interfaces between ceramics and metals is often greater than that of the ceramic component. Thus crack propagation often occurs within the ceramic component rather than on the interface itself. ESA

NUMERICAL ANALYSIS OF THE MOTION OF A RIGID BODY WITH AN ATTACHED SPRING-MASS-DAMPER M.S. Thesis
Anne E. Chinnery Dec. 1993 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273825; AFIT/GAE/ENY/93D-8) Avail: CASI HC A04

This study analyzed the stability characteristics and the unstable motion of a rigid body with a spring-mass-damper unit (nutation damper) attached parallel to one of the system's principal axes. The equations of motion are presented and non-dimensionalized. Then, they are numerically integrated over time. An analysis using a Liaponuv function develops the critical values of the moments of inertia for stability of the system, as well as the critical values of a dimensionless parameter k related to the spring constant. A discussion of the effects of the various parameters on the motion of the system is provided and some representative plots are included. The parameter b related to the distance of the nutation damper from the principal axis is found to determine whether unstable motion approaches an apparent limit cycle or a new principal axis. Parameter k affects the final position of the mass and can also influence the system toward limit cycle or equilibrium point motion. Parameter c representing the damping coefficient affects how quickly the system reaches its steady state motion. A summary of the unstable motions of the system and recommendations for further work are included. DTIC

FROST EFFECTS ON THE MICROSTRUCTURE OF HIGH STRENGTH CONCRETE, AND METHODS FOR THEIR ANALYSIS Ph.D. Thesis - Helsinki Univ. of Technology, Espoo, Finland
Heikki Kukko Dec. 1992 179 p Sponsored by Technical Research Centre of Finland, Espoo, and Alpo and Kyllikki Lippa Fund, Finland Original contains color illustrations
(VTT-PUBS-126; ISBN-9-51-384244-4; ETN-94-95236) Copyright Avail: CASI HC A09/MF A02

The aims of the study are to identify and analyze the applicability of experimental methods through studies of the freeze thaw durability of high strength concretes with different binder compositions and to elucidate the microstructural changes that occur during freeze thaw degradation. The main features of concrete microstructure, existing analysis methods, and main theories of concrete frost resistance are surveyed. Pore and crack properties of concrete were measured by automatic analysis method. Five high strength concrete mixes with various binder compositions and one medium strength concrete were prepared. They were subjected to as many as 1000 freeze thaw cycles, and the defects were studied. Strength loss was used as the basic measure of degradation. Image analysis results can be used in mathematical modeling of strength changes of concrete. Visual optical analysis of thin sections was proved to be a reliable method. Mercury porosimetry results did not give a reliable basis for the estimation of frost crack increase due to ettringite formations in the cracks. Scanning electron microscopy is a valuable tool for detecting the causes of changes found in porosimetric analysis. The principle of critical degree of saturation applies to high strength concrete. The mathematical modeling of strength loss during frost tests can be based on a combined model including changes in total porosity and maximum crack length. ESA

RICE CULTIVATION AND METHANE EMISSION: DOCUMENTATION OF DISTRIBUTED GEOGRAPHIC DATA SETS

Elaine Matthews (Hughes STX, Inc., Greenbelt, MD.), Jasmin John (Columbia Univ., New York, NY.), and Inez Fung Jan. 1994 26 p
(NASA-TM-104595; Rept-94B00030; NAS 1.15:104595) Avail: CASI HC A03/MF A01

High-resolution global data bases on the geographic and seasonal distribution of rice cultivation and associated methane emission, compiled by Matthews et al., were archived for public use. In addition to the primary data sets identifying location, seasonality, and methane emission from rice cultivation, a series of supporting data sets is included, allowing users not only to replicate the work of Matthews et al. but to investigate alternative cultivation and emission scenarios. The suite of databases provided, at 1 latitude by 1 longitude resolution for the globe, includes (1) locations of rice cultivation, (2) monthly arrays of actively growing rice areas, (3) countries and political subdivisions, and (4) monthly arrays of methane emission from rice cultivation. Ancillary data include (1) a listing, by country, of harvested rice areas and seasonal distribution of crop cycles and (2) country names and codes. Summary tables of zonal/monthly distributions of actively growing rice areas and of methane emissions are presented. Users should consult original publications for complete discussion of the data bases. This short paper is designed only to document formats of the distributed information and briefly describe the contents of the data sets and their initial application to evaluating the role of rice cultivation in the methane budget. EXPERIMENTAL EVALUATION OF CAMOUFLAGE EFFECTIVENESS IN THE THERMAL INFRARED

P. A. M. Jacobs Mar. 1993 29 p Original contains color illustrations
(Contract A90/KL/656)
(FEL-93-A043; TD93-0749; ETN-94-94953) Copyright Avail: TNO Physics and Electronics Laboratory, P.O. Box 96864, 2509 JG The Hague, Netherlands

The experimental quantification of the behavior of the apparent temperature of background elements and potential camouflage measures are discussed. The detectability of a target in the infrared spectral region is determined by differences between the radiative signatures of the target and the local background. This implies that both the temperature difference and the emissivity difference and the distribution of these differences over the target area and the background are of importance. Camouflage measures have to address both issues in order to achieve maximum signature adaptation to the background. Statistical analyses for various camouflage materials in relation to a number of background elements are given. Camouflage effectiveness is expressed in the percentage of time for which the apparent temperature contrast between the camouflage material and a background element is 1 C, 2 C, and 5 C. Analyses are performed for five consecutive weeks of measurements in the spring, the summer, and the winter, using data which were taken during a measurement campaign in 1990. ESA

A PHOTOGRAMMETRIC SOLUTION TO A PARTICULAR PROBLEM

David R. Hedgley, Jr. and Fanny A. Zuniga Washington Dec. 1993 13 p
(RTOP 505-68-71)
(NASA-TP-3415; H-1888; NAS 1.60:3415) Avail: CASI HC A03/MF A01

A closed-form mathematical solution to the classical photogrammetric problem is presented. Although quite general, the solution is more applicable to problems in which the image-space conjugates are very difficult to match but one of the elements of the pair is not. Additionally, observations are made that should make the solution to the general problem of automatic matching less computationally intensive. This approach was used to analyze flow visualization data for the F-18 High Alpha Research Vehicle. The conditions for this analysis were less than ideal for image-to-object-space transformation. A FIELD EVALUATION OF REMOTE SENSOR MEASUREMENTS OF WIND, TEMPERATURE, AND MOISTURE FOR ARM INTEGRATED SOUNDING SYSTEM RESEARCH

B. E. Martner, E. R. Westwater, and R. G. Strauch et al 1993 110 p
(Contracts DE-AI06-91RL-12089; DE-AI06-91RL-12090; DE-AI06-91RL-12092)
(DE94-000565; DOE/RL-12089/T2) Avail: CASI HC A06/MF A02

Remote sensing systems were operated in Colorado in February and March 1991 to obtain detailed profiles of the kinematic and thermodynamic structure of the atmosphere for the US Department of Energy's Atmospheric Radiation Measurement (ARM) research program. The instruments included wind profilers, radio acoustic sounding systems (RASS), microwave and infrared radiometers, an infrared spectrometer, ceilometers, radiosondes, surface meteorological stations, and other equipment. A mesoscale data assimilation model will be used to combine the data into dynamically consistent four-dimensional fields as part of an integrated data assimilation sounding system. This report evaluates the performance of the NOAA remote sensors used in the 1991 field data collection. These included five different wind profilers, each equipped with RASS capability for temperature profiling, and microwave radiometers for measurements of path-integrated water vapor and liquid water content. The design and initial testing of a Fourier-transform infrared sounder (FIRS) for humidity profiling is also described. The ranges of height coverage and measurement accuracies for each wind profiler/RASS are examined. Specific recommendations for optimizing the design and configuration of similar instruments are made for the ARM cloud and radiation testbed (CART) sites, based on results of the 1991 field work and earlier tests. Examples of routine processed data products are presented for three intensive operating period studies to further illustrate the remote sensors' capabilities. DOE

The third phase of the VIERS (Dutch acronym for preparation and interpretation of ERS-1 data) project, which was aimed at the improvement of wind extraction algorithms by development of a model, based on physics, which describes the end to end process of wind scatterometry, is reported. In order to develop such a model it was essential to gain knowledge on the scattering processes at the water surface. The experiment was carried out in wind/wave tanks (where conditions could be controlled and precisely reproduced) and on an ocean based platform. ESA

INTEGRATED USE OF HYDROLOGICAL MODELLING AND REMOTE SENSING IN THE PROVINCE OF DRENTHE (THE NETHERLANDS): POSSIBILITIES AND RESTRICTIONS
Sandra M. L. Verheijden 1992 67 p Original contains color illustrations
(Rept-61; ETN-94-95041) Copyright Avail: CASI HC A04/MF A01

For the eastern part of the Province of Drenthe (The Netherlands) an investigation of the possibilities of an integrated use of hydrological modeling and remote sensing was performed. A comparison was made between relative crop transpiration values according to the remote sensing approach and as simulated with the model SWACROP. Great deviations occurred between the relative crop transpiration values calculated with both methods. In contradiction with the expectations a more detailed SWACROP input did not improve the correspondence of SWACROP and remote sensing results. It is expected that the deviations are mainly caused by differences in temporal and spatial scale. Moreover the importance of visual interpretation of remote sensing images has proven to be a valuable tool in the validation of a seepage/infiltration map. ESA

MODES OF OCEAN VARIABILITY IN THE TROPICAL PACIFIC AS DERIVED FROM GEOSAT ALTIMETRY
Jiansheng Zou (Hamburg Univ., Germany.) and Mojib Latif Apr. 1993 40 p
(Grant EV5V-CT92-0121)
(MPIM-103; ETN-94-95110) Avail: CASI HC A03/MF A01

Satellite derived (Geosat) sea surface height anomalies for the period Nov. 1986 - Aug. 1989 were investigated in order to extract the dominant modes of climate variability in the tropical Pacific. Four modes are identified by applying the principle oscillation patterns (POP) technique. The first mode has a time scale of about three months and can be identified with the first baroclinic equatorial Kelvin wave mode. The second mode has a time scale of about six months and describes the semi-annual cycle in tropical Pacific sea level. Equatorial wave propagation is also crucial for this mode. The third mode is the annual cycle which is dominated by Ekman dynamics. Wave propagation or reflection are found to be unimportant. The fourth mode is associated with the El Nino/southern oscillation (ENSO) phenomenon. The ENSO mode is found to be consistent with the 'delayed action oscillator' scenario. The results are substantiated by a companion analysis of the sea surface height variability simulated with an oceanic general circulation model (OGCM) forced by observed wind stresses for the period 1961-1989. The modal decomposition of the sea level variability is found to be similar to that derived from the Geosat data. The high consistency between the satellite and the model data indicates the high potential value of satellite altimetry for climate modeling and forecasting. ESA

(BCRS-92-27; ISBN-9-05-411072-4; ETN-94-95039) Avail: CASI HC A04/MF A01

Part of a European remote sensing campaign which took place in Flevoland (Netherlands) is addressed. Within the framework of this campaign (MAC Europe), a DC8 aircraft carrying the three frequency (C, L and P band), full polarimetric Synthetic Aperture Radar (SAR), and an ER 2 aircraft carrying the Airborne Visible Infrared Imaging Spectrometer (AVIRIS) and the thematic mapper simulator were deployed. In addition, three CCD (Charge Coupled Device) Airborne Experimental Scanner for Application in Remote sensing (CAESAR) flights were performed in dual look mode. Also, three missions with multispectral aerial photography were performed. A detailed description of the ground truth on agricultural crops collected during the growing season of 1991 is given. A description of the test site and the farming practice of the main crops is given and the growth of selected crops, field reflectance spectra, single leaf reflectance and transmittance spectra, are described. Stereo photographs of single plants were taken. Meteorological data of the test site were provided. The leaf area index of the selected crops was ascertained from reflectance measurements. A preliminary analysis of the radiometric ground truth data is presented. ESA

APPLICATION OF ERS-1 ACTIVE MICROWAVE INSTRUMENTATION DATA TO REMOTE SENSING OF SNOW
M. Hallikainen, V. Jaeaeskelaeinen, T. Haeme (Technical Research Centre of Finland, Espoo.), and J. Peraelae (National Board of Waters and the Environment, Helsinki, Finland.) Aug. 1992 35 p
(PB93-224756; Rept-6) Avail: CASI HC A03/MF A01

Two test sites will be used to study the feasibility of the ERS-1 SAR and Wind Scatterometer for remote sensing of snow. Especially, the effect of vegetation to snow mapping is investigated. The test site in northern Finland consists of both sparsely forested areas and open areas (bogs, lakes, and clear-cut areas). The test site in North America consists mainly of agricultural prairies with lakes and some forested areas. The research plan of Finnish national ERS-1 snow program is presented. The first part includes the development of measurement and data processing techniques and preparations for the airborne measurement campaigns. In the second part satellite data, airborne data and surface data on the test site will be acquired. In the last part the capability of ERS-1 to map snow-covered ground and melting snow will be analyzed. Also, the usefulness of complementing SAR data with other types of satellite data will be examined. NTIS

SYNTHESIS OF PASSIVE MICROWAVE AND RADAR ALTIMETER DATA FOR ESTIMATING ACCUMULATION RATES OF POLAR SNOW
Curt H. Davis [1993] 6 p
(Grant NAGw-3346)
(NASA-CR-194864; NAS 1.26:194864) Avail: CASI HC A02/MF A01

In this paper, we compare dry-snow extinction coefficients derived from radar altimeter data with brightness temperature data from passive microwave measurements over a portion of the East Antarctic plateau. The comparison between the extinction coefficients and the brightness temperatures shows a strong negative correlation, where the correlation coefficients ranged from -0.87 to -0.95. The extinction coefficient of the dry polar snow decreases with increasing surface elevation, while the average brightness temperature increases with surface elevation. Our analysis shows that the observed trends are related to geographic variations in scattering coefficient of snow, which in turn are controlled by variations in surface temperature and snow accumulation rate. By combining information present in the extinction coefficient and brightness temperature data sets, we develop a model that can be used to obtain quantitative estimates of the accumulation rate of dry polar snow. THE FIFTH CALIBRATION/DATA PRODUCT VALIDATION PANEL MEETING

1992 485 p Meeting held in Boulder, CO, 7-10 Apr. 1992
(NASA-TM-108270; NAS 1.15:108270) Avail: CASI HC A21/MF A04

The minutes and associated documents prepared from presentations and meetings at the Fifth Calibration/Data Product Validation Panel meeting in Boulder, Colorado, April 8 - 10, 1992, are presented. Key issues include (1) statistical characterization of data sets: finding statistics that characterize key attributes of the data sets, and defining ways to characterize the comparisons among data sets; (2) selection of specific intercomparison exercises: selecting characteristic spatial and temporal regions for intercomparisons, and impact of validation exercises on the logistics of current and planned field campaigns and model runs; and (3) preparation of data sets for intercomparisons: characterization of assumptions, transportable data formats, labeling data files, content of data sets, and data storage and distribution (EOSDIS interface). For individual titles, see N94-23596 through N94-23617.

THE POSSIBLE EFFECTS OF THE NATURAL AND INDUCED SPACE ENVIRONMENT ON THE OPTICAL AND THERMAL PROPERTIES OF EOS SURFACES c18

Carl R. Maag and Richard A. Heppner (Perkin-Elmer Corp., Pomona, CA.) *In* NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 11 p (For primary document see N94-23595 06-43)
Avail: CASI HC A03/MF A04

Space missions, including that of EOS (Earth Observing System), will continue to be subjected to both the natural and induced space environment. The concerns associated with this fact will not go away. The NASA and DoD have recognized the need for long-life stability of materials and structures to the space environment. The major areas of interest include: thermal cycling, UV degradation, space radiation exposure, orbital debris, atomic oxygen erosion, and contamination control. Having flown a number of space environmental effects monitors, SAIC has developed both a data base to understand the magnitude of this problem and mitigation techniques to reduce the impact. DEFINITIONS IN USE BY THE VISIBLE AND NEAR-INFRARED, AND THERMAL WORKING GROUPS

Carol J. Bruegge, Ed Miller, Bob Martin, Hugh H. Kieffer (Geological Survey, Flagstaff, AZ.), and James M. Palmer (Arizona Univ., Tucson.) *In* NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 14 p (For primary document see N94-23595 06-43)
Avail: CASI HC A03/MF A04

The Calibration Advisory Panel (CAP) is composed of calibration experts from each of the Earth Observing System (EOS) instruments, science investigation, and cross-calibration teams. These members come from a variety of institutions and backgrounds. In order to facilitate an exchange of ideas, and assure a common basis for communication, it was desirable to assemble this list of definitions. These definitions were developed for use by the visible and near-infrared working group, and the thermal infrared working group. Where necessary or appropriate, deviations from these for specific instruments or other sensor types are given in the individual calibration plans. The definitions contained in this document are derived, wherever possible, from definitions accepted by international and national metrological commissions including the United States National Institute of Standards and Technology (NIST), the International Bureau of Weights and Measures (BIPM), the International Electrotechnical Commission (IEC), the International Organization for Standardization (ISO), and the International Organization of Legal Metrology (OIML). CROSS-CALIBRATION SURVEY (VISNIR)

Carol J. Bruegge *In* NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 10 p (For primary document see N94-23595 06-43)
Avail: CASI HC A02/MF A04

Included in the summary of the VISNIR survey is (1) a statement of the preferred cross-calibration approach, as endorsed by select members of the VISNIR group, (2) two viewgraphs which summarize the wavelength and fields-of-view of the various instruments, and (3) a listing of these same data, as given by the respective calibration representatives in the survey responses. The Earth Observing System (EOS) Project is fundamentally committed to the acquisition of data which can be reduced to geophysical data products of high and known accuracy. One possible method of insuring the primary data products are of known accuracy is to use the instruments themselves against the same sources to provide an independent check that a common understanding of accuracy exists. The goal then of the radiometric 'Cross-Calibration' at the integrator facility (GE) would be to convincingly establish as late as feasible in the Integration and Test (I&T) cycle that, when stimulated with common sources, the appropriate EOS instrument measurements agree within their previously established accuracy estimates across a useful radiance range, accounting for the additional uncertainty associated with the unique properties of the test set-up itself. FLIGHT SOLAR CALIBRATIONS USING THE MIRROR ATTENUATOR MOSAIC (MAM): LOW SCATTERING MIRROR

Robert B. Lee, III *In* NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 15 p Repr. from Calibration of Passive Remote Observing Optical and Microwave Instrumentation (Bellingham, WA, SPIE), v. 1943, 1991 p 267-280 (For primary document see N94-23595 06-43)

Avail: CASI HC A03/MF A04

Measurements of solar radiances reflected from the mirror attenuator mosaic (MAM) were used to calibrate the shortwave portions of the Earth Radiation Budget Experiment (ERBE) thermistor bolometer scanning radiometers. The MAM is basically a low scattering mirror which has been used to attenuate and reflect solar radiation into the fields of view for the broadband shortwave (0.2 to 5 micrometers) and total (0.2 to 50.0+ micrometers) ERBE scanning radiometers. The MAM assembly consists of a tightly packed array of aluminum, 0.3175-cm diameter concave spherical mirrors and field of view limiting baffles. The spherical mirrors are masked by a copper plate, electro-plated with black chrome. Perforations (0.14 centimeter in diameter) in the copper plate serve as apertures for the mirrors. Black anodized aluminum baffles limit the MAM clear field of view to 7.1 degrees. The MAM assemblies are located on the Earth Radiation Budget Satellite (ERBS) and on the National Oceanic and Atmospheric Administration NOAA-9 and NOAA-10 spacecraft. The 1984-1985 ERBS and 1985-1986 NOAA-9 solar calibration datasets are presented. Analyses of the calibrations indicate that the MAM exhibited no detectable degradation in its reflectance properties and that the gains of the shortwave scanners did not change. The stability of the shortwave radiometers indicates that the transmission of the Suprasil W1 filters did not degrade detectably when exposed to Earth/atmosphere-reflected solar radiation. Author

TOVS PATHFINDER PRODUCT VALIDATION AND INTERCOMPARISON Final Report

In NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 6 p (For primary document see N94-23595 06-43)

Avail: CASI HC A02/MF A04

Validation and intercomparison is an essential part of the Pathfinder program. Since its organization within the International TOVS Working Group, the TOVS community has continuously emphasized this aspect of the product retrieval problem. In the previous sections of this report, the TOVS Pathfinder SWG has recommended a careful and coherent reorganization and archiving of TOVS radiance data, and three distinct pathways for deriving product variables from this TOVS radiance archive. The importance in taking this multiple path approach to creating climate datasets rests in our firm belief that there is now global 'absolute truth' data for any of the derived physical parameters. Each of the selected methods is based upon a different set of assumptions. The challenge in interpreting Pathfinder data is to determine what alterations in the physical attributes of the environment contribute to evidence of global change extracted from observed or derived Pathfinder datasets. The Pathfinder validation and intercomparison activity must include validation of the forward problem, by which one calculates an estimate of upwelling radiance information from given earth and atmospheric data, and validation of the inverse problem, by which one calculates estimates of earth and atmospheric information from given upwelling satellite spectral radiance data. CALIBRATION OF A HELIUM-COOLED INFRARED SPATIAL RADIOMETER AND GRATING SPECTROMETER

Larry Jacobsen, Steve Sargent, Clair L. Wyatt, and Allan J. Steed *In* NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 11 p Repr. from Cryogenic Optical Systems and Instruments 4 (SPIE), v. 1340, 1990 p 217-227 Previously announced in IAA as A92-22870 (For primary document see N94-23595 06-43)

Avail: CASI HC A03/MF A04

Methods used by the Space Dynamics Laboratory of Utah State University (SDL/USU) to calibrate infrared sensors are described, using the Infrared Background Signature Survey (IBSS) spatial radiometer and grating spectrometer as examples. A calibration equation and a radiometric model are given for each sensor to describe their responsivity in terms of individual radiometric parameters. The calibration equation terms include dark offset, linearity, absolute responsivity, and measurement uncertainty, and the radiometric model domains include spatial, spectral, and temporal domains. A portable calibration facility, designed and fabricated by SDL/USU, provided collimated, extended, diffuse scatter, and Jones sources in a single cryogenic dewar. This multi-function calibrator allowed calibration personnel to complete a full calibration of the IBSS infrared radiometer and spectrometer in two 15-day periods. A calibration data system was developed to control and monitor the calibration facility, and to record and analyze sensor data. Author

Product Validation Panel Meeting 1992 18 p (For primary document see N94-23595 06-43)
Avail: CASI HC A03/MF A04

The document of ASTER Calibration Requirement specifies the following items related to spectral and radiometric characteristics of the ASTER instrument: (1) characteristics whose knowledge is specified, (2) requirement for knowledge of the characteristics, (3) methodology for characteristics evaluation, and (4) supplementary information and data related with characteristics evaluation. This document is applicable to the document of the ASTER Instrument Specification on Observational Performances, and will be a part of the ASTER Calibration Plan. ASTER Calibration Requirement is scheduled to establish the concept and framework by March 1992 when the 5th Calibration and Data Validation Panel Meeting is held, and to determine details including requirement values and evaluation methodologies by October 1992 around which the Calibration Peer Review may be held. The ASTER Calibration Plan is planned to finish by the same time.

VNIR AND SWIR TRANSFER RADIOMETERS DEVELOPED AT NRLM FOR PREFLIGHT LABORATORY CROSS-CALIBRATION
A. Ono *In* NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 28 p (For primary document see N94-23595 06-43)
Avail: CASI HC A03/MF A04

One purpose of preflight laboratory cross-calibration is to avoid the incorrect setting of instrument dynamic range due to calibration mistakes at individual instrument manufacturers. A second purpose is to make corrections of instrument responsivities to have consistent radiance scales among instruments. A third reason is to clarify the state of the art in the absolute responsivity determination of VIS/NIR and SWIF instruments in the EOS era. And fourth is the purpose of improving the preflight calibration accuracy if necessary to meet the EOS requirement. Derived from text

VALIDATING A LARGE GEOPHYSICAL DATA SET: EXPERIENCES WITH SATELLITE-DERIVED CLOUD PARAMETERS
Ralph Kahn, Robert D. Haskins, James E. Knighton, Andrew Pursch, and Stephanie Granger-Gallegos *In* NASA. Goddard Space Flight Center, The Fifth Calibration/Data Product Validation Panel Meeting 1992 8 p Sponsored by NASA, Washington (For primary document see N94-23595 06-43)
Avail: CASI HC A02/MF A04

We are validating the global cloud parameters derived from the satellite-borne HIRS2 and MSU atmospheric sounding instrument measurements, and are using the analysis of these data as one prototype for studying large geophysical data sets in general. The HIRS2/MSU data set contains a total of 40 physical parameters, filling 25 MB/day; raw HIRS2/MSU data are available for a period exceeding 10 years. Validation involves developing a quantitative sense for the physical meaning of the derived parameters over the range of environmental conditions sampled. This is accomplished by comparing the spatial and temporal distributions of the derived quantities with similar measurements made using other techniques, and with model results. The data handling needed for this work is possible only with the help of a suite of interactive graphical and numerical analysis tools. Level 3 (gridded) data is the common form in which large data sets of this type are distributed for scientific analysis. We find that Level 3 data is inadequate for the data comparisons required for validation. Level 2 data (individual measurements in geophysical units) is needed. A sampling problem arises when individual measurements, which are not uniformly distributed in space or time, are used for the comparisons. Standard 'interpolation' methods involve fitting the measurements for each data set to surfaces, which are then compared. We are experimenting with formal criteria for selecting geographical regions, based upon the spatial frequency and variability of measurements, that allow us to quantify the uncertainty due to sampling. As part of this project, we are also dealing with ways to keep track of constraints placed on the output by assumptions made in the computer code. The need to work with Level 2 data introduces a number of other data handling issues, such as accessing data files across machine types, meeting large data storage requirements, accessing other validated data sets, processing speed and throughput for interactive graphical work, and problems relating to graphical interfaces. EXPERIENCE OF THE JPL EXPLORATORY DATA ANALYSIS TEAM AT VALIDATING HIRS2/MSU CLOUD PARAMETERS
Ralph Kahn (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Robert D. Haskins (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Stephanie Granger-Gallegos (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Andrew Pursch (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), and Anthony DelGenio *In its* The Fifth Calibration/Data

Product Validation Panel Meeting 1992 28 p (For primary document see N94-23595 06-43)
Avail: CASI HC A03/MF A04

Validation of the HIRS2/MSU cloud parameters began with the cloud/climate feedback problem. The derived effective cloud amount is less sensitive to surface temperature for higher clouds. This occurs because as the cloud elevation increases, the difference between surface temperature and cloud temperature increases, so only a small change in cloud amount is needed to effect a large change in radiance at the detector. By validating the cloud parameters it is meant 'developing a quantitative sense for the physical meaning of the measured parameters', by: (1) identifying the assumptions involved in deriving parameters from the measured radiances, (2) testing the input data and derived parameters for statistical error, sensitivity, and internal consistency, and (3) comparing with similar parameters obtained from other sources using other techniques.

METHODOLOGY FOR THE ASSESSMENT OF SURFACE RESISTANCE AND SOIL WATER STORAGE VARIABILITY AT MESOSCALE BASED ON REMOTE SENSING MEASUREMENTS. A CASE STUDY WITH HAPEX-EFEDA DATA. UNESCO-INTERNATIONAL HYDROLOGICAL PROGRAM 4

W. G. M. Bastiaanssen (Winand Staring Centre, Wageningen, Netherlands.), D. H. Hoekman, and R. A. Roebeling (Winand Staring Centre, Wageningen, Netherlands.) Jul. 1993 78 p
(PB94-111721; Rept-38) Avail: CASI HC A05/MF A01

A new remote sensing algorithm has been tested with normalized difference vegetation index, surface albedo, and surface temperature data obtained during the Thematic Mapper simulator flight in the HAPEX-EFEDA field experiment (Hydrological and Atmospheric Pilot Experiment-Echival Field Experiment in a Desertification Threatened Area). Its high spatial resolution allowed for a comparison of its results with soil moisture obtained from the moisture monitoring network. The microwave backscatter coefficient derived from AIRSAR data provided a possibility to compare the evaporation and topsoil moisture content. Having the surface energy balance instantaneously quantified in a distributed manner, it was finally possible to inversely derive the surface resistance to evaporation from the latent heat flux and to study the non-linear relationship between surface resistance and soil water content at mesoscale for the Mediterranean climate present in Spain.

CLOUD-FREE AEROSOL OPTICAL DEPTH DETERMINATION OVER OCEANS FROM SATELLITE RADIOMETRY

R. Wagener, S. Nemesure, C. M. Benkovitz, S. E. Schwartz, C. M. Berkowitz (Battelle Pacific Northwest Labs., Richland, WA.), and S. J. Ghan (Battelle Pacific Northwest Labs., Richland, WA.) Jun. 1993 8 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contracts DE-AC02-76CH-00016; DE-AC06-76RL-01830)
(DE94-001897; BNL-49530; CONF-940115-7) Avail: CASI HC A02/MF A01

Shortwave radiative forcing of climate by anthropogenic sulfate aerosol has been estimated to be of comparable global-average magnitude, but opposite sign, to longwave forcing by greenhouse gases. It is therefore important that this forcing be accurately represented in climate models. Sulfate concentrations calculated by a global chemistry model driven by operational meteorological data exhibit high spatial and temporal variations that closely reproduce observations at continental sites. However, because of the sparsity of sulfate concentration measurements over oceans, aerosol optical depth determinations from satellite data are needed to evaluate the performance of the model over oceans. Previous studies of aerosol optical depths over oceans have employed advanced very high resolution radiometer global area coverage (AVHRR GAC) data that should yield the required information, but the emphasis in these studies has been to produce wide spatial coverage by time averaging for periods of a week to a month, thereby masking the high spatial and temporal variability associated with the data and required for model evaluation. The Rao et al. method is employed in the production of the weekly composite aerosol maps by NOAA since June 1987. The authors report results obtained with a modified Durkee algorithm that provides instantaneous optical depths averaged over individual GChM model grid cells (1.125 degrees x 1.125 degrees) for comparison with optical depths predicted by the chemistry model at the same times and places. The optical depth retrieval is improved by a more accurate removal of sun-glint contamination, using the formulation of Cox and Munk for sun-glint probability as a function of wind speed, together with the wind speeds available from the operational meteorological data used to drive the chemistry model.

THE EFFECT OF SUB-SURFACE VOLUME SCATTERING ON THE ACCURACY OF ICE-SHEET ALTIMETER RETRACKING ALGORITHMS

Curt H. Davis [1993] 5 p
(Grant NAGw-3346)
(NASA-CR-194825; NAS 1.26:194825) Avail: CASI HC A01/MF A01

The NASA and ESA retracking algorithms are compared with an algorithm based upon a combined surface and volume (S/V) scattering model. First, the S/V, NASA, and ESA algorithms were used to retrack over 400,000 altimeter return waveforms from the Greenland and Antarctic ice sheets. The surface elevations from the S/V algorithm were compared with the elevations produced by the NASA and ESA algorithms to determine the relative accuracy of these algorithms when subsurface volume-scattering occurs. The results show that the NASA algorithm produced surface elevations within 35 to 50 cm of the S/V algorithm, while the performance of the ESA algorithm was slightly worse. Next, by analyzing several thousand satellite crossover points from the Antarctic data set, we determined the retracking algorithm that produced the most repeatable surface elevations. The elevations derived from the S/V algorithm had the smallest RMS error for the region of the East Antarctic plateau examined here. The ESA algorithm produced erroneous estimates of elevation change when seasonal variations were present; it measured 0.7 to 1.6-m change in elevation over a 6-month period on the East Antarctic plateau where accumulation rates are only 10 cm/year.

ANALYSIS OF IMPACTOR RESIDUES IN TRAY CLAMPS FROM THE LONG DURATION EXPOSURE FACILITY. PART 2: CLAMPS FROM BAY B OF THE SATELLITE

Ronald P. Bernhard (Lockheed Engineering and Sciences Co., Houston, TX.) and Michael E. Zolensky Feb. 1994 275 p
(NASA-TM-104784; S-748; NAS 1.15:104784) Avail: CASI HC A12/MF A03

The Long Duration Exposure Facility (LDEF) was placed in low-Earth orbit (LEO) in 1984 and recovered 5.7 years later. The LDEF was host to several individual experiments specifically designed to characterize critical aspects of meteoroid and debris environment in LEO. However, it was realized from the beginning that the most efficient use of the satellite would be to examine the entire surface for impact features. In this regard, particular interest centered on common exposed materials that faced in all LDEF pointing directions. Among the most important of these materials was the tray clamps. Therefore, in an effort to better understand the nature of particulates in LEO and their effects on spacecraft hardware, residues found in impact features on LDEF tray clamp surfaces are being analyzed. This catalog presents all data from clamps from Bay B of the LDEF. NASA Technical Memorandum 104759 has cataloged impacts that occurred on Bay B (published March 1993). Subsequent catalogs will include clamps from succeeding bays of the satellite. Author (revised)

PANEL TO REVIEW EOSDIS PLANS Final Report
1994 94 p
(Contract NASw-4627)
(NASA-CR-195088; NAS 1.26:195088) Copyright Avail: CASI HC A05/MF A01

Formed in Jan. 1992, the Panel to Review EOSDIS Plans was charged with advising NASA on its plans for developing the Earth Observing System (EOS) Data and Information System (EOSDIS). Specifically, the panel was asked to do the following: assess the validity of the engineering and technical underpinnings of the EOSDIS; assess its potential value to scientific users; suggest how technical risk can be minimized; and assess whether current plans are sufficiently resilient to be adaptable to changing technology and requirements such as budget environments, data volumes, new users, and new databases. The panel completed an interim report (Addendum A) and transmitted it to NASA and other interested parties in the government on 9 Apr. 1992. Because of a delay in NASA's plans to select the contractor for EOSDIS, the panel was not able to complete its review of the program according to the original government request. With the issuance of a letter report (Addendum B) on 28 Sep. 1992, the panel became inactive until such time as NASA could release the details of the contractor's proposed architecture, schedule, and costs for developing EOSDIS. In early 1993, NASA awarded the contract for the EOSDIS Core System (ECS). On 20 Apr. 1993, NASA asked the panel to reconvene to do the following: (1) complete its review of NASA's approach to the EOSDIS architecture and implementation; (2) appraise NASA's responses to the panel's previous recommendations; and (3) review the planning for EOSDIS in the context of NASA's role in the Global Change Data and Information System (GCDIS) implementation plan. To respond to the NASA charge, the panel met three times in 1993 including sessions with NASA officials and the EOSDIS contractor. In addition, several of the panel members visited individual Distributed Active Archive Centers (DAAC's) to obtain additional views of EOSDIS. The panel has now obtained substantial information on the EOSDIS budget, contractor work program, and current baseline architecture that was not previously available, due to procurement restrictions. This report presents the panel's findings and recommendations based on this additional information. Author (revised)

MAPPING TOMORROW'S RESOURCES: A SYMPOSIUM ON THE USES OF REMOTE SENSING, GEOGRAPHIC INFORMATION SYSTEMS (GIS), AND GLOBAL POSITIONING SYSTEMS (GPS) FOR NATURAL RESOURCES MANAGEMENT
Allan Falconer, ed. 1993 93 p Symposium held in Logan, UT, 23-24 Apr. 1992; sponsored by Utah State Univ., S. J. and Jesse E. Quinney Foundation, the Soil Conservation Service, the Fish and Wildlife Service, Forest Service, and Utah Geographic Alliance *Its* Natural Resources and Environmental Issues, Volume 2
Copyright Avail: Issuing Activity (Quinney Library, Coll. of Natural Resources, Utah State Univ., Logan, UT 84322-5260)

The College of Natural Resources recognizes the important role it has in educating natural resources managers and leaders who can provide the guidance and knowledge needed to increase the production of the earth's renewable resources while sustaining and enhancing the global environment and the natural resource base. The College's teaching, research, extension, and service efforts focus on the many aspects of sustained multiple-natural-resources management and their relationship to man. Through its many programs, the College of Natural Resources focuses on solving local, state, national, and global problems to enhance a more efficient and contemporary use of the world's natural resources. Natural Resources and Environmental Issues (NREI) which began publication in 1993, is a technical series that addresses current topics relevant to natural resources and to the environment. The journal is published as a series of volumes, with at least one being issued each year as the proceedings of the Natural Resources Week Symposium. In the issue on Mapping Tommorrow's Resources, the following topics are discussed: Natural Resource Information from Monopoly to Competition; Global Resources and Mission to Planet Earth; Geographic Information Systems (GIS) Systems and Data Management for Global Data Sets in Natural Resources; the Global Resource Information Database; Overview of GIS Technology in Utah State Government; Politically Correct Global Mapping and Monitoring; Integrating Satellite Imagery and GIS into Natural Resources Management; Forest Service Applications of Remote Sensing and the National Training Program; the Position of the Global Positioning System (GPS) in Wildlife and Habitat Mapping; and the Bureau of Land Management's (BLM's) Remote Sensing Program in Utah. FACTORS AFFECTING THE IDENTIFICATION OF PHYTOPLANKTON GROUPS BY MEANS OF REMOTE SENSING
Ellen C. Weaver (San Jose State Univ., CA.) and Robert Wrigley Jan. 1994 121 p
(RTOP 199-30-92-14)
(NASA-TM-108799; A-94022; NAS 1.15:108799) Avail: CASI HC A06/MF A02

A literature review was conducted on the state of the art as to whether or not information about communities and populations of phytoplankton in aquatic environments can be derived by remote sensing. In order to arrive at this goal, the spectral characteristics of various types of phytoplankton were compared to determine first, whether there are characteristic differences in pigmentation among the types and second, whether such differences can be detected remotely. In addition to the literature review, an extensive, but not exhaustive, annotated bibliography of the literature that bears on these questions is included as an appendix, since it constitutes a convenient resource for anyone wishing an overview of the field of ocean color. The review found some progress has already been made in remote sensing of assemblages such as coccolithophorid blooms, mats of cyanobacteria, and red tides. Much more information about the composition of algal groups is potentially available by remote sensing particularly in water bodies having higher phytoplankton concentrations, but it will be necessary to develop the remote sensing techniques required for working in so-called Case 2 waters. It is also clear that none of the satellite sensors presently available or soon to be launched is ideal from the point of view of what we might wish to know; it would seem wise to pursue instruments with the planned characteristics of the Moderate Resolution Imaging Spectrometer-Tilt (MODIS-T) or Medium Resolution Imaging Spectrometer (MERIS). AN INVESTIGATION OF CURRENT AND FUTURE SATELLITE AND IN-SITU DATA FOR THE REMOTE SENSING OF THE LAND SURFACE ENERGY BALANCE Final Report, Nov. 1989 - Jan. 1994
George R. Diak Feb. 1994 24 p
(Grant NAGw-1858)
(NASA-CR-195138; NAS 1.26:195138) Avail: CASI HC A03/MF A01

This final report from the University of Wisconsin-Madison Cooperative Institute for Meteorological Satellite Studies (CIMSS) summarizes a research program designed to improve our knowledge of the water and energy balance of the land surface through the application of remote sensing and in-situ data sources. The remote sensing data source investigations to be detailed involve surface radiometric ('skin') temperatures and also high-spectral-resolution infrared radiance data from atmospheric sounding instruments projected to be available at the end of the decade, which have shown promising results for evaluating the land-surface water and energy budget. The in-situ data types to be discussed are measurements of the temporal changes of the height of the planetary boundary layer and measurements of air temperature within the planetary boundary layer. Physical models of the land surface, planetary boundary layer and free atmosphere have been used as important tools to interpret the in-situ and remote sensing signals of the surface energy balance. A prototype 'optimal' system for combining multiple data sources into a three-dimensional estimate of the surface energy balance was developed and first results from this system will be detailed. Potential new sources of data for this system and suggested continuation research will also be discussed. Author

HYDRAULICS AND MORPHOLOGY OF MOUNTAIN RIVERS: A LITERATURE SURVEY. COMMUNICATIONS ON HYDRAULIC AND GEOTECHNICAL ENGINEERING

A. Sieben Jan. 1993 148 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-110772; Rept-93-4) Avail: CASI HC A07

The report is a literature survey of recent research on mountain rivers. The study aims to describe or refer to research on fluvial processes of mountain rivers from a hydraulic and morphological point of view. With this survey, an attempt was made to describe the state of the art on the subject and to distinguish priorities in research. In Chapter Two, attention is paid to the general characteristics of mountain rivers compared to low-land rivers. Chapter Three describes general hydraulic processes and includes a review of the formulation of resistance to flow. In Chapter Four, the morphological features of mountain rivers are described. Movements of sediment are described in Chapter Five, which concentrates on the rate, composition, and mode of sediment transport. Effects of a changing rheology of flow due to high rates of sediment transport are described briefly in Chapter Six. Here, also remarks can be found on discharge measurements and prediction of solute transport in mountain rivers. Conclusions are presented in Chapter Seven, where recommendations are made on topics of further research. NTIS

METHOD FOR SELECTION OF WAVELENGTH BANDS FOR MULTISPECTRAL CLASSIFICATION [METOD FOER VAL AV VAGLAENGDSBAND VID MULTISPEKTRAL KLASSIFICERING]

M. Ulvklo Nov. 1992 85 p In SWAHILI Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-204378; FOA-C-30688-3.1) Avail: Issuing Activity (National Technical Information Service (NTIS))

Multispectral technics are normally used for civil and military satellite remote sensing. Multispectral images from six wavelength bands in the visual range already exist at FOA Linkoping. The images are recorded in ground level and contain a vehicle in outdoor scenes. The main objective in the final project is to investigate if the result of object detection in the images is good enough if only three wavelength bands are used instead of all six. In the final project a maximum likelihood multispectral classifier is used for segmentation of areas which can be vehicles. For these areas a number of statistical features are computed. The features are extracted from the first principal component which is calculated with Hotelling transform. Evidential reasoning is used to determine if the areas are vehicle or not. A method of selection of the optimal subset of wavelength bands has also been worked out in the final project. The idea of the method is to use the covariance matrix to achieve the subset of wavelength bands that is most uncorrelated. A comparing study shows that the number of false targets increases with a factor of four when only three wavelength bands are used instead of six. The result is therefore not satisfying when only three wavelength bands are used. NTIS

TOOLS FOR VISUALIZING LANDSCAPE PATTERN FOR LARGE GEOGRAPHIC AREAS

S. P. Timmins (Analysas Corp., Oak Ridge, TN.) and C. T. Hunsaker 1993 10 p Presented at the 2nd International Workshop in Integrating Geographic Information Systems and Environmental Modeling, Breckenridge, CO, 27-29 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE94-001121; CONF-9309230-2) Avail: CASI HC A02/MF A01

Landscape pattern can be modelled on a grid with polygons constructed from cells that share edges. Although this model only allows connections in four directions, the programming is convenient because both coordinates and attributes take discrete integer values. A typical raster land-cover data set is a multimegabyte matrix of byte values derived by classification of images or gridding of maps. Each matrix may have thousands of raster polygons (patches), many of them islands inside other larger patches. These data sets have complex topology that can overwhelm vector geographic information systems. The goal is to develop tools to quantify change in the landscape structure in terms of the shape and spatial distribution of patches. Three milestones toward this goal are as follows: (1) creating polygon topology on a grid, (2) visualizing patches, and (3) analyzing shape and pattern. An efficient algorithm has been developed to locate patches, measure area and perimeter, and establish patch topology. A powerful visualization system with an extensible programming language is used to write procedures to display images and perform analysis. DOE

EVALUATION OF THE USE OF REMOTE-SENSING DATA TO IDENTIFY CROP TYPES AND ESTIMATE IRRIGATED ACREAGE, UVALDE AND MEDINA COUNTIES, TEXAS, 1989

Lee H. Raymond, Gregory M. Nalley, and Paul L. Rettman 1992 58 p
(PB93-193159; USGS/WRI-92-4117) Avail: CASI HC A04/MF A01

Remote-sensing data were used to estimate that 190,000 acre-feet of water was pumped from the Edwards aquifer in 1989 to irrigate crops in Uvalde and Medina Counties. Landsat digital satellite images for March and July 1989 were combined and classified to identify the areas of crops irrigated with water from the Edwards aquifer in the two counties. Normalized difference, the difference between the infrared and red reflectance values divided by the total of those values, was used to discriminate vegetative from nonvegetative ground cover. The images subsequently were classified using maximum likelihood, an unsupervised classification procedure. Detailed vegetation distribution maps of two calibration sites in the study area, and boundaries of the areas probably irrigated in 1989, helped to interpret the results and to separate probable irrigated areas from the rest of the image. Results were verified using crop acreages reported by the U.S. Department of Agriculture. Irrigated-crop areas subsequently were multiplied by the respective duties of water to calculate the total quantity of water pumped from the aquifer for irrigation. NTIS

DEVELOP ADVANCED NONLINEAR SIGNAL ANALYSIS TOPOGRAPHICAL MAPPING SYSTEM Technical Progress Report

Jan. 1994 25 p
(Contract NAS8-39393)
(NASA-CR-195128; NAS 1.26:195128; TR-4002-94-01) Avail: CASI HC A03/MF A01

The Space Shuttle Main Engine (SSME) has been undergoing extensive flight certification and developmental testing, which involves some 250 health monitoring measurements. Under the severe temperature, pressure, and dynamic environments sustained during operation, numerous major component failures have occurred, resulting in extensive engine hardware damage and scheduling losses. To enhance SSME safety and reliability, detailed analysis and evaluation of the measurements signal are mandatory to assess its dynamic characteristics and operational condition. Efficient and reliable signal detection techniques will reduce catastrophic system failure risks and expedite the evaluation of both flight and ground test data, and thereby reduce launch turn-around time. The basic objective of this contract are threefold: (1) develop and validate a hierarchy of innovative signal analysis techniques for nonlinear and nonstationary time-frequency analysis. Performance evaluation will be carried out through detailed analysis of extensive SSME static firing and flight data. These techniques will be incorporated into a fully automated system; (2) develop an advanced nonlinear signal analysis topographical mapping system (ATMS) to generate a Compressed SSME TOPO Data Base (CSTDB). This ATMS system will convert tremendous amount of complex vibration signals from the entire SSME test history into a bank of succinct image-like patterns while retaining all respective phase information. High compression ratio can be achieved to allow minimal storage requirement, while providing fast signature retrieval, pattern comparison, and identification capabilities; and (3) integrate the nonlinear correlation techniques into the CSTDB data base with compatible TOPO input data format. Such integrated ATMS system will provide the large test archives necessary for quick signature comparison. This study will provide timely assessment of SSME component operational status, identify probable causes of malfunction, and indicate feasible engineering solutions. The final result of this program will yield an ATMS system of nonlinear and nonstationary spectral analysis software package integrated with the Compressed SSME TOPO Data Base (CSTDB) on the same platform. This system will allow NASA engineers to retrieve any unique defect signatures and trends associated with different failure modes and anomalous phenomena over the entire SSME test history across turbo pump families. DEVELOP ADVANCED NONLINEAR SIGNAL ANALYSIS TOPOGRAPHICAL MAPPING SYSTEM Technical Progress Report
Jen-Yi Jong Dec. 1993 16 p
(Contract NAS8-39393)
(NASA-CR-194785; NAS 1.26:194785; TR-4002-93-12) Avail: CASI HC A03/MF A01

As reported in the monthly technical progress report for July 1993, a new signal analysis technique called instantaneous frequency correlation (IFC) for time delay estimation was developed which will be incorporated into the ATMS system. In this report, a different technique for time delay estimation called phase difference time derivative estimator (FDTDE) will be discussed. The FDTDE technique does not replace the IFC method since their application conditions are different. The IFC technique can estimate the time delay between two spectral components of two measurement signals when the center frequency of the components is constant, while the FDTDE method can provide accurate time delay estimation when the frequency of the subject component changes linearly such as during engine startup or shut-down. ADVANCED RESEARCH AND TECHNOLOGY DEVELOPMENT OF MCFCs
T. G. Benjamin, R. J. Remick, and R. A. Donado 1993 9 p Presented at the Joint Contractors Meeting on Advanced Turbine Systems, Fuel Cells and Coal-Fired Heat, Morgantown, WV, 3-5 Aug. 1993
(Contract DE-AC21-90MC-27394)
(DE94-001918; DOE/MC-27394/94/C0263; CONF-930893-6) Avail: CASI HC A02/MF A01

The objective is to lower contact resistance losses associated with protective oxide layer that forms on the surface of stainless steel in the MCFC (molten carbonate fuel cell) cathode environment. The approach being taken is to coat the top surface of the stainless steel with a thin film of iron oxide. A 316L stainless steel sheet metal was coated with 3-micron thick layer of Fe2O3 using jet vapor deposition. The films were examined by SEM/EDX and the conductivity measured. Resistance of cell with only a 316L separator was 0.116 ohm, while that of the cell with the iron oxide coated separator was 0.124 ohm. DOE

Results and conclusions of the final phase (3) of a three-year research program on polycrystalline thin-film heterojunction solar cells is described. The research consisted of the investigation of the relationships between processing, materials properties, and device performance. This relationship was quantified by device modeling and analysis. The analysis of thin-film polycrystalline heterojunction solar cells explains how minority-carrier recombination at the metallurgical interface and at grain boundaries can be greatly reduced by the proper doping of the window and absorber layers. Additional analysis and measurements show that the present solar cells are limited by the magnitude of the diode current, which appears to be caused by recombination in the space charge region. Developing an efficient commercial-scale process for fabricating large-area polycrystalline, thin-film solar cells from a research process requires a detailed understanding of the individual steps in making the solar cell, and their relationship to device performance and reliability. The complexities involved in characterizing a process are demonstrated with results from our research program on CuInSe2 and CdTe processes. DOE

PROGRESS IN PHASES 2 AND 3 OF THE PHOTOVOLTAIC MANUFACTURING TECHNOLOGY PROJECT (PVMaT)
C. E. Witt, R. L. Mitchell, G. D. Mooney, L. O. Herwig (Department of Energy, Washington, DC.), D. Hasti (Sandia National Labs., Albuquerque, NM.), and R. Sellers (Solar Energy Industries Association, Washington, DC.) Oct. 1993 6 p Presented at the 23rd Institute of Electrical and Electronic Engineers (IEEE) Photovoltaic Specialists Conference, Louisville, KY, 10-14 May 1993
(Contract DE-AC02-83CH-10093)
(DE94-000206; NREL/TP-411-5501; CONF-930540-11) Avail: CASI HC A02/MF A01

This first year of the process-specific activities of the Photovoltaic Manufacturing Technology (PVMaT) project was completed, and the first subcontracts for teamed efforts on R&D of a general nature were awarded. A second solicitation for process-specific research and development (R&D) is in the evaluation stage for award of subcontracts. The technical accomplishments of the first process-specific subcontracts (Phase 2A), the status of the teamed research (Phase 3A), and the status of the solicitation for the second process-specific solicitation (Phases 2B) are described. A NOVEL METHOD FOR DETERMINATION OF TRANSPORT PARAMETERS OF H2 AND O2 IN PEMFCs
Masanobu Wakizoe, J. Kim, S. Srinivasan (Texas A&M Univ., College Station.), and J. McBreen 1993 14 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993
(Contract DE-AC02-76CH-00016)
(DE94-001492; BNL-49537; CONF-930571-27) Avail: CASI HC A03/MF A01

A knowledge of the transport parameters of hydrogen and oxygen in proton exchange membrane fuel cells (PEMFC's) is of vital importance for the following: (1) an elucidation of the kinetics of the half-cell reactions; (2) analyzing mass transport phenomena in the electrodes and membranes; (3) estimating the cross-over currents during fuel cell operation; and (4) evaluating membranes from different manufacturers and selecting the most promising candidate. Previous studies to determine diffusion coefficients and solubilities of H2 and O2 in proton conducting membranes have rarely been made under fuel cell operating conditions.This paper deals with novel approaches to determine the transport parameters in PEMFC's using steady state and transient techniques. The transient technique proved to be the most desirable for this purpose. Experiments were conducted in PEMFC's with Asahi Chemical Aciplex(TM)-S Membranes and DuPont's Nafion(TM)-117 membranes. The diffusion coefficients (D) of H2 and of O2 are higher in the Nafion(TM) membranes, while their solubilities (C0)

are higher in the Aciplex(TM) membranes. The D values are higher for O2 than for H2 in both membranes while the opposite behavior is the case in respect to C0 values. The values of activation energies for diffusion of H2 or O2 in the membrane are of the same order as in aqueous electrolytes. There is an anomalous temperature dependence of the solubilities of H2 and O2 in the two membranes. This is not the case with the product DC0. The diffusion rate of H2 through the membranes is higher than that of O2.

MODELLING OF SOLID POLYMER AND DIRECT METHANOL FUEL CELLS: PHENOMENOLOGICAL EQUATIONS AND ANALYTICAL SOLUTIONS

P. S. Kauranen 7 Apr. 1993 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-224897; TKK-F-C149) Avail: CASI HC A04

In the solid state concept of a direct methanol fuel cell (DMFC), methanol is directly oxidized at the anode of a solid polymer electrolyte fuel cell (SPEFC). Mathematical modelling of the transport and reaction phenomena within the electrodes and the electrolyte membrane is needed in order to get a closer insight into the operation of the fuel cell. In the work, macro-homogenous porous electrode and dilute solution theories are used to derive the phenomenological equations describing the transport and reaction mechanisms in a SPEFC single cell. The equations are first derived for a conventional H2/air SPEFC, and then extended for a DMFC. The basic model is derived in a one dimensional form in which it is assumed that species transport take place only in the direction crossing the cell sandwich. In addition, two dimensional descriptions of the catalyst layer are reviewed.

MATHEMATICAL MODELING OF MCFC CELLS/STACKS AND NETWORKS

M. C. Williams, J. Wimer, F. Sudhoff, and D. Archer (Carnegie-Mellon Univ., Pittsburgh, PA.) 1993 8 p Presented at the 206th American Chemical Society (ACS) National Meeting, Chicago, IL, 22-27 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print
(DE94-001914; DOE/METC-C/94/7109; CONF-930802-15) Avail: Issuing Activity (Department of Energy (DOE))

In this paper, various molten carbonate fuel cell (MCFC) cell/stack, network, and system models available in the public domain are discussed. Parametric and phenomenological fuel cell mathematical models are being used to simulate individual MCFC cell/stack performance. With initial demonstration of full-area, full-height 250-kW to 2-MW MCFC power plants, the spatial configuration of the MCFC stacks into networks in the fuel cell power plant takes on new importance. MCFC network and power plant system flowsheet performance is being modeled using the ASPEN system model. ASPEN is a tear and iterate flowsheet simulator in the public domain. ASPEN is suitable for MCFC network simulation since it has strong systems and property database capabilities. With emergence of larger MCFC power plant system demonstrations, system modeling of MCFC power plants is now essential. DOE routinely uses MCFC models in making performance comparisons and in decision making.

(DE93-018221; NREL/TP-411-5739-Phase-2A) Avail: CASI HC A03/MF A01

This report describes work done under a subcontract to significantly advance the photovoltaic manufacturing technologies, reduce module production costs, increase average module performance, and increase the production capacity existing at Utility Power Group (UPG) and Advanced Photovoltaic Systems, Inc. (APS). Areas of focus include the following: (1) encapsulation and termination, (2) product design, (3) process and quality control, and (4) automation. UPG will improve its encapsulation system through the development of advanced encapsulation materials and processes that result in a module that does not require backing glass. In addition, UPG will work to develop advanced termination materials and processes. APS will perform development activities centered on the EUREKA manufacturing line. Developments in the APS EUREKA encapsulation system will be in addition to the UPG activity on encapsulation and will offer an alternative approach to the problems of encapsulating large-area thin-film modules.

NOVEL TWO-STAGE SELENIZATION METHODS FOR FABRICATION OF THIN-FILM CIS CELLS AND SUBMODULES

B. M. Basol, V. K. Kapur, A. Halani, and C. Leidholm Oct. 1993 20 p Prepared for Midwest Research Inst., Golden, CO Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC02-83CH-10093)
(DE94-000220; NREL/TP-413-5844) Avail: CASI HC A03

This is the Phase 1 Annual Technical Progress Report of a subcontract enitled Novel Two-Stage Selenization Methods for Fabrication of Thin-Film CIS Cells and Submodules. The objectives of the program are the development of a cost effective process for CIS film deposition, optimization of various layers forming the CIS solar cell, and fabrication of submodules using these processes and devices. During this first phase of the program, the authors have completed their 1 sq ft size processing capabilities and added to their facilities an in-line sputtering system that can handle up to 1 sq ft size substrates. They have optimized the sputtering conditions for the Mo contact as well as the Cu and In films. Thickness uniformity of the Cu and In layers have also been optimized by masking the magnetron cathodes to obtain a variation of 3% throughout a sq ft substrate. Using the resulting films, they have demonstrated their first large area CIS submodules with outputs of about 3W/sq ft. Addition of a computer controlled mechanical scriber to the fabrication facilities, and optimization of the large-area ZnO layers are expected to improve the power output of these submodules to over 5W/sq ft shortly. In addition to the large-area submodule work, the authors have also carried out research aimed at the development of a non-vacuum processing approach for the growth of CIS layers. They have deposited films using this technique, and small-area cells with over 10% conversion efficiency have been demonstrated on such CIS layers.

This document contains the proceedings of NASA's fourth Space Electrochemical Research and Technology (SERT) Conference, held at the NASA Lewis Research Center on April 14-15, 1993. The objective of the conference was to assess the present status and general thrust of research and development in those areas of electrochemical technology required to enable NASA missions into the next century. The conference provided a forum for the exchange of ideas and opinions of those actively involved in the field, in order to define new opportunities for the application of electrochemical processes in future NASA missions. Papers were presented in three technical areas: advanced secondary batteries, fuel cells, and advanced concepts for space power. This document contains the papers presented. For individual titles, see N94-23346 through N94-23367.

APPLICATIONS OF X RAY ABSORPTION FINE STRUCTURE TO THE IN SITU STUDY OF THE EFFECT OF COBALT IN NICKEL HYDROUS OXIDE ELECTRODES FOR FUEL CELLS AND RECHARGEABLE BATTERIES

Sunghyun Kim, Donald A. Tryk, Daniel A. Scherson, and Mark R. Antonio (Argonne National Lab., IL.) *In* NASA. Lewis Research Center, Space Electrochemical Research and Technology Nov. 1993 p 13-19 Sponsored in part by DOE (For primary document see N94-23345 06-44)

Avail: CASI HC A02/MF A03

Electronic and structural aspects of composite nickel-cobalt hydrous oxides have been examined in alkaline solutions using in situ X-ray absorption fine structure (XAFS). The results obtained have indicated that cobalt in this material is present as cobaltic ions regardless of the oxidation state of nickel in the lattice. Furthermore, careful analysis of the Co K-edge Extended X-ray absorption fine structure data reveals that the co-electrodeposition procedure generates a single phase, mixed metal hydrous oxide, in which cobaltic ions occupy nickel sites in the NiO2 sheet-like layers and not two intermixed phases each consisting of a single metal hydrous oxide. Avail: CASI HC A03/MF A03

Thermodynamic parameters for Nickel-Cadmium (NiCad) and Nickel-Hydrogen (NiH2) batteries are calculated for temperatures ranging from 273.15K (0 C) to 373.15K (100 C). For both systems, we list equilibrium and thermoneutral voltages for the cells, and in the case of the NiH2 battery, these data are provide for hydrogen fugacities ranging from 0.01 to 100 (atm) to simulate the full discharged and charged states. The quality of the input thermodynamic data are assessed and the effect of assuming different cell reactions is analyzed. Author

HIGH SPECIFIC ENERGY, HIGH CAPACITY NICKEL-HYDROGEN CELL DESIGN

James R. Wheeler *In* NASA. Lewis Research Center, Space Electrochemical Research and Technology Nov. 1993 p 41-47 (For primary document see N94-23345 06-44)

Avail: CASI HC A02/MF A03

A 3.5 inch rabbit-ear-terminal nickel-hydrogen cell was designed and tested to deliver high capacity at steady discharge rates up to and including a C rate. Its specific energy yield of 60.6 wh/kg is believed to be the highest yet achieved in a slurry-process nickel-hydrogen cell, and its 10 C capacity of 113.9 AH the highest capacity yet of any type in a 3.5 inch diameter size. The cell also demonstrated a pulse capability of 180 amps for 20 seconds. Specific cell parameters and performance are described. Also covered is an episode of capacity fading due to electrode swelling and its successful recovery by means of additional activation procedures. Author (revised)

HIGH SURFACE AREA, LOW WEIGHT COMPOSITE NICKEL FIBER ELECTRODES

Bradley A. Johnson, Richard E. Ferro, Greg M. Swain, and Bruce J. Tatarchuk *In* NASA. Lewis Research Center, Space Electrochemical Research and Technology Nov. 1993 p 49-60 (For primary document see N94-23345 06-44)

(Grant NAG3-II54)

Avail: CASI HC A03/MF A03

The energy density and power density of light weight aerospace batteries utilizing the nickel oxide electrode are often limited by the microstructures of both the collector and the resulting active deposit in/on the collector. Heretofore, these two microstructures were intimately linked to one another by the materials used to prepare the collector grid as well as the methods and conditions used to deposit the active material. Significant weight and performance advantages were demonstrated by Britton and Reid at NASA-LeRC using FIBREX nickel mats of ca. 28-32 microns diameter. Work in our laboratory investigated the potential performance advantages offered by nickel fiber composite electrodes containing a mixture of fibers as small as 2 microns diameter (Available from Memtec America Corporation). These electrode collectors possess in excess of an order of magnitude more surface area per gram of collector than FIBREX nickel. The increase in surface area of the collector roughly translates into an order of magnitude thinner layer of active material. Performance data and advantages of these thin layer structures are presented. Attributes and limitations of their electrode microstructure to independently control void volume, pore structure of the Ni(OH)2 deposition, and resulting electrical properties are discussed.
